To Aspirants for Success:

It is well known that the greatest advance in the control of disease has been through prophyla tic and therapeutic immunization.

What in the entire history of medicine compares to the results achieved in the

control of cholera, plague, small pox, hydrophobia, whooping cough, meningitia,

typhoid feve typhus and many other diseases by the use of vaccines?

Do you realize that equally wonderful results can be achieved in the treat ment of pneumonia, broncho-pneumonia, rheumatic fever bronchitis puerperal septs, to, with appropriate bacterins and that the physician of the future will be the one who is a skilled immunologist? If you are not acquainted with the rapid strides made in this wonderful field of immunization you owe it to yourself and your nationts to become informed at once.

Dr Sherman's New Book on Vaccine Therapy

Just of the press with 500 pages of live material. By the way do you know why few dead organisms injected under the skin will produce more immunity during an infection than the live organism consists the infection? This and many other thangs are rationally explained. SEND YOUR ORDER TODAY

Don t fail to visit our Exhibit at The Clusteal Congress of Surgeons in Philadelphi

Dr. Howard A Kelly's Stereo-Clinic

IT is universally conceded that the only way to keep posted on all the advances made in Surgery is to visit Clinics. The up to date surgeon must see the operation itself. The formation of Clinical Societies in various cities and towns as well as the Clinical Congress of Surgeons of North America, is proof of the growing necessity of seeing clinical work.

It is in recognition of these facts that

Dr Howard A. Kelly's Stereo-Clinic

was inaugurated and is now being published and kept up-to-date

A Few of the Many Expressions of Appreciation

Hugh H Young M D Johns Hopkens Medical School, Balt more, Md "If anyons studies the Steroot y ks. made of my opera on, he will see more than be can by witness if g the operation itself.

W Jackson MD FR.FP.S Nelson, Lancashire, England.

"I am ours you deserve the thanks of the whole surgical world for producing such valuable and permanent work, which will be the more appreciated the more it as studied

H Augustus Wilson M D Prof of Orthopedic S rgery Jefferson Medical College Philadelphia, Ps.

College Finitely processed with the also of the STEREO CLINICS as I find hev gi informs on that could only be bladed by being present alon that no operator who I doi g the work. They are naisenly profess.

A. F. Jonas M.D. Prof. Singers College of Medicine, University of Nebraska, Omaha Nebraska.

I have DR HOWARD A. KELLV'S STERGO-CLINIC and the strengerme are spleadedly essected illustrating operations by many of our best surgions. I most bearnly reconsisted to every extraout her TERRO-CLINIC

Fred H. Albae M.D. Prof. Orthopedic Surgery University of Vermoot, Adj. Prof. Orthopedic Surgery Columbia University New York.

I must say that I believe that anyone will get better idea of the tack sque from these bea in f I sterson that from the front row in the amphitheutre. The perspect re and detail is wonderful.

George W Dobbin M D College of Physica and Surgeons, Baltimore, Md
The pictures are the fibest I have ever seen. It is cartually most graphic method of short g
operations and you deserve great cred to for haring tolored them.

than a merely comfortable condition. At tacks will recur with lowered general resistance bad weather conditions etc.

Its first occurrence is as a rule late after sexual life has terminated. There comes a gradual recognition of undue frequency of urination with tenesmus and burning From time to time in its course the acute exacerba tions may be severe and occasion much loss of sleep and worry resulting in distinct physical and mental impairment. Such sharp attacks may persist for weeks, followed by months of comparative comfort. The urine at its worst, may be clouded with mucus and pus, and occasionally though rarely blood stained I have never seen a unne that was grossly thick and ropy with pus and mucus, as we often see it in cystitis cases in younger individuals and in old prostatics.

The bacteriological findings have been variable and in no way consistent. Staphy lococci are practically always in evidence colon bacilli and allied forms occasionally in one case a chain bacillus whose place in the nomenclature we never determined Tubercle bacilli we have never found to be a factor in spite of the sometimes suggestive appearance. The smegma bacillus was almost invariably present unless excluded by care in procuring the specimen. In short, in those cases that we have studied a determina tive infection has not been identified. It may not be a specific infection and this is our be lief but a condition developing after many differing bacterial onslaughts in bladders already weakened by the processes of senile decay Again, many of the forms that we find may be saprophytic there as a result of favorable soil conditions rather than as causative factors.

One of our active workers along the lines of surgical pathology suggested that I might find these cases to be secondary to various degrees of prolapse following the lacerations and relaxations of pregnancy. He thought that the prolonged air and clothing contact with perversion of secretions would in part account for the senile vaguitus and that this might be the primary source of infection with the bladder condition secondary. Certainly in several of my more recent cases this

has not been true and I am skeptical of it as definitely etiological

One of the illustrations here shown is an extreme case in an unmarried woman of sixty four my only exception to the rule of the multipara. Here the vagina would only admit the little finger and there was nothing of relaxation or prolanse.

Often the bullous patches are sharply out lined in grouping from healthy perfectly normal bladder mucosa, as distinctly so as a Zoster cruption on the skin. This has suggested the possibility of its being akin to a recurrent chronic Herpes. Without going into lengthy discussion this theory hardly appeals to me as being adequate to explain the allied changes in the rectal and vaginal microuse.

Almost without exception the condition is common to bladder vagina, and rectum simultaneously. The chinical picture of senile vaginities is so common that I shall not take time to comment on it except to say that it is always present and recognized that it most often receives all the attention and treatment for rulei of the sometimes vague pelvic distress when it is only one of the trialty of troubles.

The vaginal change is usually looked upon as a shinkage of subcutaneous tissues with atrophic disturbances in the epithelium and resulting painful enosons or even ulcerations. Add to this be terial invasion with infimum tory crudates and the future course is not difficult of imagination. If this brief para graph is true applied to sende vaganitis, I believe it holds equally true of the accompanying bladder change and of the almost consistently present degeneration of rectal mucosa.

The vagina has not been included in the accompanying illustrations in spite of its in anable participation. I have presented however the rectal picture to accompany each bladder drawing. The rectal mucosa has varied in its appearance all the way from multiple punctate crosions to large distinct punched out areas of ulceration on an other wise normal plut velvety base but still a darker ground shade than applies to a normal bladder.

At this point the question of syphilis might

in other nucous membranes. Bronchitis in the old becomes almost the rule. A chronic conjunctivitis with thickened and everted hids is all too common. Nasopharyngeal cutarrh in the old becomes the bane of the family physican. Perhaps this bladder difficulty has simply to be added to that group

The general management of these old women will be apparent the best of general care and hygienic control The usual bot bonc irrigations are quickly beneficial Argyrol in instillation is helpful. The rectal and vaginal irritation can perhaps best be met by the hot alkaline douche the interval of douching being gauged by the comfort obtained Vicorous local treatment, such as applica tion of strong silver I have felt to be out of place since the problem seems to be one more of comfortable management than of cure Pure hauid gualacol internally is a drug possessing almost specific properties. It al most invariably brings remarkable and cuick relief from the frequency of urination with tenesmus and burning when given in five to ten drops doses after each meal. Its use is in a way empiric. Some one has claimed that its benzoic and radical is broken up and eliminated by the kidneys as hippuric acid. This being a normal urinary acid may play some definite part in the relief which we do not pretend to explain. It may be re sorted to whenever discomfort is experienced and taken for indefinite weeks or put ande perhaps for many months during the intervals of comparative comfort.

To discuss cellular and tissue changes due to age decay along purely beological lines as has been so ably done by Metchinkoff and many others is not my province yet I do feel that in this group of cases has been over looked a pathological entity worthy of better recognition and a name Tentatively I suggest cystiss sentiles feminarum for lack of a better

than a merely comfortable condition. At tacks will recur with lowered general resistance bad weather conditions etc.

Its first occurrence is, as a rule late after sexual life has terminated. There comes a gradual recognition of undue frequency of urination with tenesmus and burning time to time in its course the acute exacerba tions may be severe and occasion much loss of sleep and worry resulting in distinct physical and mental impairment. Such sharp attacks may persist for weeks followed by months of comparative comfort. The urine at its worst may be clouded with mucus and pus, and occasionally though rarely blood I have never seen a urine that was grossly thick and ropy with pus and mucus as we often see it in cystitis cases in younger individuals and in old prostatics.

The bacteriological findings have been variable and in no way consistent. Staphy lococci are practically always in evidence colon bacilli and allied forms occasionally in one case a chain bacillus whose place in the nomenclature we never determined Tubercle bacilh we have never found to be a factor in state of the sometimes suggestive appearance. The smegma bacillus was almost invariably present unless excluded by care in procuring the specimen In short in those cases that we have studied a determina tive infection has not been identified. It may not be a specific infection and this is our be hef but a condition developing after many differing bacterial onslaughts in bladders already weakened by the processes of senile decay Again, many of the forms that we find may be saprophytic there as a result of favorable soil conditions rather than as causative factors

One of our active workers along the hose of surgical pathods; suggested that I might find these cases to be secondary to various degrees of prolapse following the lacerations and relaxations of pregnancy. He thought that the prolonged air and clothing contact with perversion of secretions would in part account for the senile vagnitist and that this might be the primary source of infection with the bladder condition secondary. Cer tainly in several of my more recent cases this

has not been true and I am skeptical of it as definitely ctiological

One of the illustrations here shown is an extreme case in an unmarried woman of sixty four my only exception to the rule of the multipara. Here the vagina would only admit the little finger and there was nothing of relaxation or prolapse.

Often the bullous patches are sharply out lined in grouping from healthy perfectly normal bladder mucesa, as distinctly so as a Zoster cruption on the skin. This has suggested the possibility of its being akin to a recurrent chronic Herpes. Without going into lengthy discussion this theory hardly appeals to me as being adequate to explain the allied changes in the rectal and vaginal nucesse.

Almost without exception the condition is common to bladder vagina, and rectum simultaneously. The chinical picture of senile vaginitis is so common that I shall not take time to comment on it except to say that it is always present and recognized that it most often receives all the attention and treatment for relief of the sometimes vague pelvic distress when it is only one of the trinity of troubles.

The vaginal change is usually looked upon as a shrinkage of subcutaneous tasses with atrophic disturbances in the epithelium and resulting painful crosions or even ulcerations. Add to this bacterial invaseon with inflammin tory erudates and the future course is not difficult of imagination. If this brief para graph is true applied to sendle vaginitis. I believe it holds equally true of the accompanying bladder change and of the almost consistently present degeneration of rectal nucosa.

The vagina has not been included in the accompanying illustrations in spite of its in variable participation. I have presented however the rectal picture to accompany each bladder drawing. The rectal mucosa has varied in its appearance all the way from multiple punctate erosions to large distinct upon the property of the property of

At this point the question of syphilis might

CHAPLTON CYSTITI E ILIS FEVIL 1

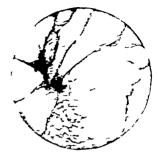

Fig 6 Case 3 Superficially eroded prearance in patches throughout rectal pouch. Accompanies Fig 5 opearance in

in other mucous membranes. Bronchitis in the old becomes almost the rule. A chronic conjunctivitis with thickened and everted lids is all too common. Nasopharyngeal entarrh in the old becomes the bane of the family physician Perhaps this bladder dif ficulty has samply to be added to that group

The general management of these old women will be apparent the best of general care and hygienic control. The usual hot boric irrigations are quickly beneficial Argyrol in instillation is helpful The rectal and vacunal irritation can perhaps best be met by the hot alkaline douche the interval of douching being gauged by the comfort obtained Vigorous local treatment, such as applica tion of strong silver I have felt to be out of place nance the problem seems to be one more of comfortable management than of cure. Pure liquid guaiacol mternally is a drug possessing almost specific properties. It al most invariably brings remarkable and quick rehel from the frequency of urination with tenesmus and burning when given in five to ten drops doses after each meal. Its use is in a way empiric Some one has claimed that its benzoic acid radical is broken up and chminated by the kidneys as hippuric acid This being a normal unnary acid may play some definite part in the relief which we do not pretend to explain. It may be re sorted to whenever discomfort is experienced

and taken for indefinite weeks or put ande perhaps for many months during the intervals of comparative comfort.

To discuss cellular and tissue changes due to age decay along purely biological hnes. as has been so ably done by Metchinkoff and man; others is not my province yet I do feel that in this group of cases has been over looked a pathological entity worthy of better recognition and a name Tentatively I suggest cystitis sendis temmarum for lack of a better

Mrs W ag 60, multipara previou health good first experienced bladder symptoms at 64. At that tim I found cystoscopically pra tically the same conditio as when examined re cently At this later examination Fig. (frontispiece) was take n which gives the typical petchy grouping of vesicles seen at the height of ttack. She has had several long periods of complete relief during these years Figure (rectal) accompanying sh wa dustinct el nguted ulcerati just above the internal sphincter bleeding on touch with cotton awab

CARE CASE Mrs. C go 7 multipara previous health good mild bladder symptoms presented bout the age of 50 Some years later was cysto scoped, the bladder showing irregular patchy orderns. Recently during an interval of comfort Fig 3 (fro tisplece) was taken and presents the typical pigmented ppearance and chronically thickened vessel walls remaining after repeated acute exacerbations. Figure 4 shows n ulcerated eroded area in the rectum. This patient has suffered from a m cous collids f twenty years.

CASE 3 Mrs. O age 38 mother of one child. Not that she has not menstrusted since that child birth thirteen years ago (cause unknown) During these years she has grown very heavy until her obesity has become a burden t her Bladder sympt ms first developed nine m nths ago There have been hort intervals f relief Figure 5 (frontispiece) taken during an exacerbation, shows the typical vesicular patchy losion at the height of an ttack. This is the one exception t my series in point f age, yet here we had, years ago an typical pathological menopeuse so that the and rectum present superficially congested erosive areas, Fig. 6 presenting granulated appearance f th rectal m coan.

Case 4 Mrs. L ge 68 multipara previous

Case 4 Mrs. L ge 68 multipara previous health good. At 56 slight bladder trouble first became evident with variable intervals of relief since. It has been more persistent during the last three years. January 3 96 she presented the most extrem cystitus of this vesiculated patchy form that I had ever seen. I brought her back March 5 to get picture, which is shown in Fig. 7

(frontispiece) Greath to my disappointment the appearance had entirely changed so that we wronly able to get the interval picture with it apparent pigmentation of mucosa and increased n twork of vessels but no externations elevations or irregularities as seen previously. The rectal picture fails to show any of the lesions ordinarily found in these cases.

CASE 5 Ms & MeN single age 64. This is the one exception to mis experience in the factor is childbirth but in as much as hillbraining is regarded as only contributory the ear pit in simal be tound more frequently than I hiv until quarther than the contribution of the more papeared in February 1015 when he had a rattal lasting three months. Since then had a intervals of contort.

A few of the visicular elevation have become putular and one large clear bleb the 121 of a plant apparent. The vagina and rectum both how advanted atrophic eroded areas.

Figure 8 (rectal) how the same v si ular I sion becoming purulent as found in the blad let. The artist has somewhat evaggerated the jurulent character of these vesicles.

A suggested in an earlier paragraph the criticum may be offered that Fig. 8 i rather typical of tuberculosi. I admit the imilanty but believe that during the coming sum mer months this bladder may be cy to-soped

I Epodpith nimeta paanaminitii Iham ji ppan hiilden Ik (a

and will be tound to correspond to Fig. , and 4. I have found this to be true in imilar cases and bear in mind that the woman has hid interval of entire relief ince the onset of her symptom, and the history does not typically coincide with tuberculosi.

SPONTANEOUS EXCLUSION OF THE KIDNEY FROM CALCULI

By CHARLES M. HARPSTER PROC. M.D. I.A.C.S. T. (1.08. Onto

A case I think positively demon strates that renal and ureteral lithing asis may entirely destroy a kidney insidiously and at the same time exclude the organ completely. Such a kidney is entirely out of the urogenital wistem and is of no further use to the patient and surely better out of the body than left in If you will examine the specimen carefully you will see the ureter is entirely occluded.

The patient from whom this kidney was r moved was a female 37 years of age married and the mother of one child. She was referred to me by Dr. H. E. Aoble, on August 4, 1015. She stated at the time of examination that she had had pain on her left side since her child was born about 12 years.

That for four or five y are he had felt a ago ma on her left sil which wa gradually getting larger. For the last three or four months she stated she had had great pain at time of menstruation and that a large amount of pu-was discharged from the vacina at time of menstruation. During the summer of 913 had had pell of chills an fever and was ompelled to remain in bed a part o At tim's the pain in the left side was very acute an l at other times would entirely disappear. The urine had been frequently examined and found free from any abnormal elements Dur ing the period of her pregnancy the urinary symptoms were very marked and when voiding urin she had a bearing down burning pain I made an examination of her urine and found it normal

I referred the patient to Dr Dolloway for an \(\bar{\chi}\) ray examination and I present the roentgenogram in which you will see the large calcule (Fig. 1)

Fig Roentgenogram dycloong large calcult.

I catheterised the right uneter on August 6 9 3 and found no none coming from the left kidney with catheter in the bladder a d I was unable to pass catheter into the left unter The left kidney did not respond t ny of the functional tests (polhoridan, polhades and die carmine). The right kidney was found in trust.

A few does here Very

A few days later I removed the specimen which is shown in Figs. 2 and 3. The parenchyms of the kidney was as you see almost entirely destroyed. The cavity was filled ith caseous mass. No tubertic bacill were tound on exam nation.

By operation the question arises whether we deprived the patient of a possible pus focus, since the organ had been apontane ously excluded by nature (Fig. 3). For haps only in so far as the ureter affected the vesical function could the presence of the organ have produced any climical manifestations and even this is open to doubt Buerger says.

Although this process of bealing or ex 1 d of the kidney (seed, as a has loo been termed auto-nephrectomy) has been lequently noted as occurring in tuberculous, it is not so well kno that similar leason may be the entitled of creat laids as when the eter has become batra red for long time. So I expent is the development of the infectious type of lesion of the kidney hen are terral calculus is impacted for a long time to

ureter that most of us will conced that to I destruct in of a kidney it bout pyone phrosis, without other manifestation of in affected pelvis or kidney parenchyma or libout perirenal tissues is exceedingly rare.

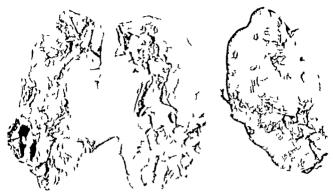

It was our good fortune to btain at an autory's a specimen of a kidney and ureter which demonstrated conclusively that a kid ney may be destroyed and evoluted as symptoms, when ureteral calcule raune teral calcule is impacted in the ureter for many years. In reviewing the literature but some more than the control of these facts could be found

B Rank in an article entitled Concerning

a Case of Healed Hydropyonephrous scribes a case of infected hydronephrotic kid nev which by virtue of an obstruction situated high in the ureter became converted into a sac filled with cheesy mortar like mat mal kidney was obtained at an autopsy of a man who died of appoolery The fortal lobulations were fairly well marked by furrows separat ing many spherical protuberances the latter varying in size from a hazelnut to a walnut, Upon section the kidney which was hardly enlarged, was found filled with a cheesy mass of cement like consistency The parenchyma was practically gone there being hardly any renal substance left except for remnants in the membranous walks and in the connectivetussue septa. Only at one point was there a small zone of tixsue less than 1 m in diam In short the specimen denoted the fol lowing pathological history that a hydronephrotic sac had evidently become the seat of supporative inflammation wa thus con verted into pyonephrosis, the purulent contents becoming finally changed into inspissated cheesy masses.

In discussing the causes of the hydronephrous in this case the author concludes that the obstruction must have resided somewhere in the uteropelvic juntion and hasnuch as no widence of concretions. realcult were present he believes that either an in flammatory swelling of the mucous more brane or a calculus that had subsequently passed could have brought about the condition.

National Arch | Path, State, et Berl en h

lig Specimen remodel in the

Lucy partner runs I from uther s

From a study of the author report it seems to us most likely that the hydronephrous could be best explained on the bill of an occlusion of the urcter by a calculu that had been arrested for a long time but had finally been expelled. The proces of renal destruction a 1 seen in tuberculosi ot long standing where kidney to ue di appears and pseudocy to may form to often encountered where the calve ha completely stenosed. With an ob-truction of a calve it is not frequent to see complete di integration of the corresponding segment of the kidney and the conversion of the at tected region into a sac tilled with chec v material or turbid fluid. In the way some of those cy is of the kidney may be accounted for the pathogenesis of which has given rise t so much comment and di cu ion. There

ire those who doubt the exitence of tuber culous cyst of the kidney Heitz Boyer however describes two types of tubercu lou ev t. hrst true ev t of the kidney in which epithchum covers the cavities and which coexist (renal tuberculosi) and ec ondly pocket which are the result of obtruction of a urinary pa sage of the kidney a where a cally a completely occluded. It the occluded zone i healthy a simple hydro nephrosi i the result and contents of the civity will be clear fluid. It on the con trury the area be the seat of a tuberculou proces the civity will become filled with cheesy material and the will become mode ned later on either into a putty like ma r if the material be absorbed into a fluid which contain some whiteh particles and detritu

DIVERTICULA OF THE URINARY BLADDER

By G. J. THOMAS M.D. ROCHESTER, MINACESOT From the Mayo Close.

THE frequent occurrence of diverticula of the bladder as observed in the urologic department of the Mayo Chnic has suggested a clinical study of the operative non-operative, and post mortem cases since 1008

Embryology A review of the literature and textbooks of embryology as to the early d velopment of the bladder is confusing Many of the early writers are of the opinion that the anlage of the bladder is a different rated portion of the allantors and is derived from thi structure Later writers, however hold that the bladder is formed from the cloaca, a blind sac which is a dilated portion of the primitive gut caudal to the allantois The cloacal membrane probably divides this sac into a ventral or large portion which be comes the urogenital sinus, and a dorsal smaller portion which becomes the rectum I rentise (1) however from his dissections thinks that a saddle-like partition b tween the primitive gut and allantois grows caudally and divides the cloaca into dorsal rectum and a ventral primitive urogenital sinus. The par tition thus made fuses with the closcal mem brane and divides it into the anal membrane of the gut and the urogenital membrane of the urogenital sanus. The mesonephric ducts which opened into the cloaca now open into this sinus. The buds forming the ureters spring from the mesonephric ducts near their insertion into the clouca. As the urogenital sinu gradually becomes separated and differ entiated from the rectum, certain absorptive changes take place in the proximal ends of the mesonephric ducts and primitive ureters. They become dilated are taken up into the wall of the anus, and as the absorption con tinues the ends of the ureters develop a separate opening and become separated from the ducts. The area between the ends of these two sets of ducts later becomes the point of division between a larger cephalic part of the sinus or the anlage of the bladder

and a smaller caudal portion which becomes the weethra

The etiology of these sacs from Etiology an embryologic standpoint can probably be explained as follows. The diverticulum so frequently seen around the meati may be anomalies of mesonephric duct buds which normally form the ureters etc. as Cabot and Binney pointed out from Huntington s case. Since portions of the wolffian ducts are taken up into the bladder and form a portion of it, anomalies of development may occur along the trigone and floor of the urethrn as far a. the ejaculator, ducts. The mucosa of the bladder is largely endodermal in origin except the trigone which together with the floor of the urethra is mesodermal The fallure of the urachus to close may ac count for some of the sacs at the roof of the bladder. These observations indicate that anomalies of embryologic development may at least predispose to the formation of these diverticula since most of them occur where fumon takes place between the different embryonic ussues. The location of the open ings is most often in the areas where anomalies may be expected. The rôle that obstruction plays in the formation of these anomalies is not clear but clinically in a large percentage of cases it seems necessary for the development of symptoms

Diverti ula may be divided into two groups

congenital and acquired

1 The congenital may be divided into (a) hour-glass bladder the strangulation may be above or below the ureters (b) double split or bind bladder. In this type the sepa ration reaches to the apex of the tingone and both (as) ties open into a common urethra or a d uble urethra may be present.

2 The acquired type may be divided ac cording to their etiology into (a) intra uterine (b) obstacles to urination (most frequent)

and (c) traumatic

he anlage of the bladder. The true congenital variety as observed.

Fur Small diverticula, probabl congental

uey contaming tones was dispussed from rountgen and crystococyce findings. About one half mch anterior to the right ornice and toward the median lin was another opening which rould dmit th end of the small finger. Upon observation p parent sparts of i rij clear urine could be seen but these seemed to be synchronous with respiration. A catheter was passed with apparent ease and did not feel as if it coiled up. Argyrol as i jected into the bladder and cysta-oneterogram was made. This showed a satonge shaped shadow extending from the bladder to to be bony pelvis of the right side where it was lost (Fig.). A had as ing catheter was passed into the right ureter which was found in a normal position and del on mpty into och wave ny connection in the normalou cavity. This patient had had a pel ic operation. Which traums of the bladder may have occurred and which might have bee the etiologic fact. In producing the sa

In the diagnosis of diverticulum of the bladder in patients having suggestive symptoms Garratt (8) makes it a practice to distend the bladder with an opaque medium He believes that the diagnosis can easily be made by this means, and that it should be used routinely because in many instances cystoscopic findings are not positive

In operating on a case of hour glass bladder Squier used two large champs through the liverticulum opening and by resection between the champs and statching up the cutedges a large bladder or sac was made. He does not recommend this operation in all cases but thinks it applicable when the diverticulum is of the hour glass type.

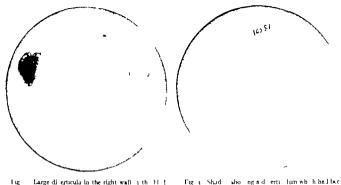

In Youngs (9) case in which there was a papilloma he used a circular incision made from the vesical adde surrounding the opening of the diverticulum. By blunt dissection the surrounding tissues were dissected off and it was necessary to remove a piece of the perioneum. The peritoneum was closed through the vesical opening. This method is suggisted by Young to remove diverticula and tumors which are situated on the posterior wall of the bladder and behind the ureteric ocenings.

Lower (10) suggested the introduction of a gauze strip into the sac to simulate a semi solid tumor which makes its size easily seen and facilitates its removal. Edwin Beer (17) suggests the introduction of catheters into the areters before operation is begun so that the ureters are easily found and constantly in view especially where transplantation is to be done.

Lerche (12) by means of a rubber bag attached to the end of a catheter and distended after introduction into the neck both increases the size of the divertifulum and makes resection easy. Lerche reports the following routes for radical operation

- A Vaginal route
- B Sacral route
- C Suprapula intrapentoneal
- D Suprapuble extraperit neal
- The various simpler methods which are used are

 A Incurrent through the vaginal wall and
- A Incision through the vaginal wall and drainage.
- B Establishing of fistula by sewing to the
- skin
 - C Peritoneal drainage behind blad fer D Peritoneal drainage of bladder

Large di erticula in the right wall 1 th 11 ! der Shalow project up in that of the bladder

arefull it ted with arg rol through in reterral Argyrol tall I t pa int the bladder

L Forable tretching of the orifice of diverticulum

F Curettement of mucous membrane of the diverticulum and suture of the latter without drainage

G Invagination of diverticulum and blad der freshening of the margin of the oritice and closure intraperitoneally

H Enlargement of the ornice of commu nication between the diverticulum and the bladder or a new anastomosis

I Division of the walls of the bladder and diverticulum and suture of the cut walls J Suprapubic drainage

Englisch (2) reports fifty seven cases of diverticula up to 1904 in which there was perioration or rupture. He divides the cases that are most hable to perforation or rupture into four classes (1) Chronic type with accumulation of pus and mucus (2) acute suppurative (3) ulcerating and gangre nous and (4) perforating In his opinion the location of the opening of the diverticulum in the bladder and its size are important tactors entering into subsequent inflammation perforation etc

In cases collected by Fischer there was a mortality in operative and non-operative cases of 66, per cent in operative cases to per cent and in non-operative of 84 s per cent

From January 1008 to November 1915 twenty seven cases of diverticulum of the bladder have been observed in the Mayo Clinic Lourteen of these patients were operated on seven were not operated on and six cases were found at autopsy average age of these patients was 51+ years the youngest 18 and the oldest 73 The average age at on-et of symptoms was 43+ years Other than these numerous cases were observed which were regarded as false diverticula probably the result of me chanical obstruction or inflammatory changes These cases are not included in this report Previous diseases Of these twenty seven patients six (22 per cent) gave a history of urethral infection and two (7 per cent) had infection about the urethra associated with stricture Five patients (18 per cent) had had previous operations two for prostatic obstruction and three some operation on the bladder for drainage or exploration Six (22 per cent) had trauma of the bladder supra pubic area or of the perineum. The trauma

to the perineum in two cases was the cause

of obstruction which preceded the symptoms. The four remaining patients gave good histones of onset of symptoms immediately following the trauma of the bladder.

Urinary symptoms Difficulty of urina tion was present in nineteen instances (70 per cent) and was noted in eleven (40 per cent) as the first symptom. In nine there was retention and catheterization had to be resorted to before urine could be massed. In three there was incontinence Frequency was a first symptom in nine (33 per cent) and was the predominate symptom in twenty two Hamaturia was the first agn observed by the patient in two instances (7 per cent) while macroscopic blood was observed at some time during the history in eight (20 per cent) We were able to obtain a history of repeated urination from one patient only a symptom which has been frequently noted in published reports. In only two of our pa tients the symptoms began in childhood

Circial dala A suprapulse tumor was palpable in only three cases (11 per cent) in none was a flank or rectal mass observed in eleven cases (ap per cent) a noticeable loss in weight was reported and this seemed to be the most common clinical finding. In six (22 per cent) the general loss of strength was graded as three on a scale of four.

Cycloscopic data Cystoscopic examinations were made in nineteen of our patients. In sixteen (84 per cent) there was a marked de gree of cystitus. In three (15 per cent) cancer was found in the bladder In one case at post mortem a cancer was found in the diverticulum and was the cause of a perforation Stones were found in the blad der in four (21 per ent) in one they were found with a cancer There were three cases with multiple small stones in the diverticulum Urethral stricture was noted in three (15 per cent) and was thought to be an etrologic factor in the production of the diverticula. In eight (42 per cent) the prostate was enlarged enough to cause obstruction to urination.

Location of opening of dreviuulum. The opening of the diverticulum was found near the menti in six of the twenty seven patients on the right side in two and on the left in

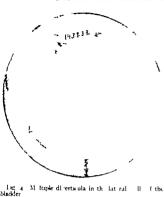

four In an others the opening was found on the floor of the bladder in two near the ure thru in four on the potentor wall in two in the dome in three the lateral walls were in volved in one an hour glass condution was found. In the three remaining cases the opening was on the poeterior wall or base. In four cases there was more than one diverticulum. In thirteen cases generalized trabeculation of the bladder was present.

Roenteen-ray 1 cystogram was mad in sixteen cases ten showing positive findings In our opinion a routine cystogram in sus pected cases in which there I difficulty of urination not otherwise diagnosed either with or without the aid of the cystoscope will demonstrate a diverticulum in a large per centage of cases. Care must be taken in exposing the plates Many shadows of diverticula are missed when the radiogram is taken in the ordinary anteroposterior position. Exposures should be made with the tube at different angles so that the shadow of the sac is not superimposed on that of the bladder A couled shadow-casting cuthe ter or bougie will definitely outline a sac when shadow-casting fluids cannot be used Care must be taken in the introduction of catheters into these sacs, and overdistention from injected fluids must be avoided because perforation of the diverticulum might occur (Figs. 2 3 4, 5 and 6)

Urindlysis Pyuria was present in seven teen cases and gross blood was noted in

Medical treatment Symp tomatic treatment does not relieve patients of their symptoms and should be used only when surgical measures are contra indicated. Temporary relife is sometimes obtained but recurrence is sure.

Surgeal treatment In fourteen cases some type of operation was performed In steel the diverticulum was resected. The extra peritoneal operation was done four times and the intraperitoneal two \(^1\) preliminary drainage was done in two \(^1\) two preliminary drainage was done in two cases preparation to a resection. In Bix instances a drainage operation only was done or the diverticular opening was enlarged. In one case a septum was removed and in one a diverticulum was

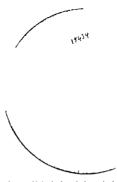

dissected loose and it opening enlarged so

that the dramage was improved or complete Completed Completed to the Completed that I have ensured with an hour glass contracture of the bladder the mass in the upper chamber—stones were removed in three patients two having stones in the diverticula. It was necessary to remove the prostate in six instances. The prostates all proved to be beingin. Dilatation of the ureter was found in one. In only one case was there evidence of perforation or of peritonitis

This occurred in a man of o year who ame

to the Clinic complaining of a long standing skin trouble. For a number of years he had slight difficulty with urination and was quite sure that he was not emptying his bladder. He was in very poor physical condition and a complete examination was not made. Urinary lifficulty became so troublesome that he was confined to his bed He had a sudden attack of pain in the lower abdomen increase in temperature and pulse rate and ollapse He seemed to pass a fair amount of urin and catheterization was not done for fear of pre cipitating an attack of uramia which was the ten tative diagnosis. He died in 4 or 5 days before a positive diagnosis had been made. At autopsy a moderate degree of hypertrophy of the prostate together with three diverticula were found. One of the diverticula had ruptured because of a cancer which it contained The diverticulum was situated along the posterior wall of the bladder

 $1\ \mathrm{g}\ \mathrm{g}$. Multiple discreticul in the lateral all it the bladd

Evidence of pendiverticulity with result ant adhesions was present in every patient. The difficulty of removal in most instances made a careful examination of the diverticulum impossible. In three patients per sitent post operative in tula developed which did not heal for several months. Pvelone phritis was a complication in four stone with pyonephrosis in one. In one instance only did the ureters open into the diverticula and the condition was blateral.

In the six cases in which resections were done there were no deaths of these patients died some weeks after leav ing the hospital probably from acute renal infection. Two patients had drainage preparatory to resection one of these died ()ne other had a carcinoma in an hour glass blad der and died after suprapubic drainage. In one case in which there were large stones in an enormously distended bladder with a diverticulum the patient died from the effects of suprapubic drainage. In six instances a diverticulum was discovered at autopsy one of these patients had had a severe renal in fection one had had a few pus-cells in the urine in the remaining cases there were no urinary finding These patients did not have symptoms which could make a diagnosis of

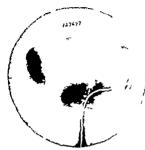

Fig. 6 Shadow cauding catheter carefully couled to diverticula 1 the left lateral wall of the biolder

diverticulum probable except the one with renal infection. In the cases complicated by carcinoma, stones or severe renal infection, the mortality is high.

Post mortem findings A review of the poet mortem findings above some interesting facts. Marked pyelonephritis was found in 80 per cent and was considered the major factor in causing death. A severe grade of nephritis was found in 78 per cent. In 55 per cent there had been severe centities and in two the inflammation in the diverticulum was more marked than that in the bladder. Two patients died of poeumonia

CONCLUSIONS

The embryology of the bladder is not clear and in only a few cases does incomplete development account for the pathology. In some instances the condition may be congenital but other factors seem necessary be fore symptoms develop.

- 2 In this group the average age of onset (43+ years) would indicate that acquired factors (obstruction 86 per cent) seem necessary for the development of diverticula clin loalis.
- 3 Trauma was a factor in 22 per cent 4 The cystogram and leaded catheter are of great aid in diagnosis and may be the only positive findings.
- 5 Surgery is the best method of treatment The choice of operation depends on the location and size of the diverticulum.
- 6 When resection is possible the mortality is negative. In complicated cases the mortality is high because of renal and vesicle infection.

THE TREATMENT OF GENERAL TUBLECULOSIS IN THE MALE!

BY JOHN II CENNINGHAM JR MID I ICS BEST N

THE material upon which this communication is based is from the post mortem and clinical data of the Boston City. Hospital the Long Island Hospital where there is a large tubercular camp private cases and a survey of the literature.

Post mortem inding have been included first because examinations at autop y are more accurate than clinical observation and serve to establish the frequency of co-existing tubercular lesions in the different structures of the genital tract second because it i frequently impossible to detect clinically the presence of tubercular lesions in the prostate and vesicles when tuberculosis of the epidid ymis is obvious, third because in tubercular epididymitis it is of great importance to know the probability of similar lesions in the other organs of the genital tract when they are apparently normal by every mean of clinical examination fourth it is of great value to know the frequency with which renal and vesical tuberculosi 1 to be ex pected together with tuberculosi of the cpi didymis and fifth it is possible by post mortem examination to learn how frequently other organs such as the lung bone etc are tubercular also Such information it seem to me must be the groundwork upon which our maccurate chinical methods of observa tion stand and it is from the actual knowl edge or if not actual knowledge the likeli hood of the presence of the infection in the remainder of the tract that appropri ate treatment should be based

1utopsy hadings In 4 50 autopsy record I have been able to find 35 instances of the beroilosts of the epidalymis the most common lesion of the genital tract to be observed clinically in which a microscopical examination as well as a gross description of the condition of the prostate and vesicles is recorded Of these 35 cases the disease was bulateral in the epidalymis in 15 and in 20 it was unilateral—right 12 left 8. In these 35 cases the vesicles were involved in 25 and the prostate and the p

tate in 25. It is seen that in each in tance where the vesicle was involved the pro-tate wa involved also and that there were 10 in tances where the condidymi was the only tructure of the track affected, which give good reason for the belief that the disease i usually primary in this organ. Of the rebilat eral cases involvement of the eminal vesi cles was bilateral in re and unilateral in a Of these 35 cases the to tick wa involved In 4 of the case involving the could vesicles and prostate with a calcou tuberculosis there was an acute miliary tu berculosis of all the visceral organs which wa, the probable cruse of death. In all of the other cases the primary cause of death was other than tuberculosis of the genital organ In many of these in tances of tu berculosi of the epididymis just mentioned the lesions in the prostate or vesicle were not and in fact could not be detected by rectal palpation because in some it was only on microscopical examination of the traues that the le ion were detected

Of these 15 cases the bladder was involved 16 times and the kidney showed unilateral tuberculo is in 11 and bilateral infection in 5. Tuberculosis of other structures occurred as follows lung 31 bone 5 intestines 8 ischiorectal absects 3 some of the cases showing multiple lesions. In this series of 4250 autoposes there were two instances of caseous tuber culosis of the prostate without involvement of the vesicles or epididymis. In one there was no other focus of tuberculosis in the body except in the lung and in the other both kidneys and the bladder were tuberculous and at the same time there was a lung focus.

Clinically an analysis of the cases of tu bercular cpiddymitis series to substantiate the post mortem findings in some degree but the discrepancies in demonstrating the high relative co existence of the disease in the different organs of the whole tract, from the clinical data to follow must be attributed as previously stated to the inability to dem

onatrate the lessons clinically as frequently as they exist.

Of 86 patients showing a tubercular epidid ymis, where the records are satisfactor, 41 showed palpable lesions on the vesicles and 49 in the prostate while 37 showed no palpable lesions in the vesicles or prostate

In many of the instances where the vesicle and prostate were typically tubercular amears of the material expressed from them showed the tubercle bacillus in less than 15 per cent of the cases examined.

Of these 80 clinical cases the bladder and kidneys were examined in 51. The bladder was tubercular in 16 there was unilateral renal tuberculosis in 9 and bilateral in 5 and in 2 no renal tuberculosis could be demon strated. In three cases there was a tuber culosis of the hip and 5 had Potts disease one had tuberculosis of the shoulder Joint

and 67 had distinct signs in the lungs. A consideration of the literature both post mortem and clinical adds further evidence which lead one to the conclusion that tuber culosis of the genital tract in the male is most common in the epididymis where it is often primary occurring as a hematogenous infection and from the epididymis the disease extends along the vas, either by con tinuity or lymphatics to the esicles and prostate Walker in his remarkable monograph Studies in the Experimental Produc tion of Tuberculosis in the Genito urinary Oregus states that secondary tuberculosis of the vesicles occurs in about 60 per cent of all the cases of genito-urinary tubercu lous and as shown in my post mortem find ings when the vesicles were involved the prostate was involved also (25 out of 35 cases)

There is much evidence to support this view Simmonds found in a series of 35 cases of genital tuberculosis that the vesicles were infected in 29 and the prostate in 26 Oppenheum in a series of 27 cases found the vesicles invaded in 17 and the prostate in 18 Kraywicki in a series of 15 cases showed the vesicles tubercular in 11 and the prostate in 14. Collinet in a series of 70 cases found the vesicles involved in 36 and the prostate in 14. Saxtorph, in a series of 547 instances of genital tuberculosis found at autopsy records

.....

but two instances where the only demonstrable lesion was in the vesicles and 9 cases where the only lesion was in the prostate Teutschlaender in a series of 57 cases found but a single example of tuberculous con hied to the veucles. Guiss in a series of 183 cases of genital tuberculous found but to involving the prostate and vesicles alone Social and Burchlandt record 44 clinical cases of genito-urinary tuberculous and found no instance when but single tructure was in volved.

The question of whether tuberculosis oc curs as a primary lesion in the prostate or vesicles as far a the genital tract is concerned is of only passing interest gards the prostate it must be considered extremely rare but an autopsy record by Crandon and two by Kraywicki and the two cases in my series show that the prostate may rarely be the only organ of the genital tract to be infected. In regard to the vest the autopsy indings of Saxtorph. Teutschlaender Oppenheim Orth Drever and others must lead to the belief that this structure may be the only one of the tract to harbor tuberculous yet the vesicles, like the prostate are usually infected from a tubercular process in the epididymis or kid From this evidence it is not to be nre sumed that when the vesicles give clinical signs of a tubercular process, these structures are the only part of the genito-unnary tract

involved. It may be adely concluded therefore from the post mortern and clinical data that when tuberculosls is present in the epidlid, miss there are tubercular leasons in the vest cles and prostate in most instances whether they can be demonstrated clinically or not

Treatment It is upon this well founded assumption that treatment should be based. There are those who recognizing leasons in all the different organs of the tract recommend and have practiced a total removal of the genutal tract. On the other hand there are those who recognizing the same condition advocate no surgical procedure but rely on general hygienic measures symptomatic treatment and tuberculin. Between these two extreme points of view we have

those who advise simple drainage of tuber cular abscess or removal of the scrotal lesion either by enididymectomy or castration leaving the disease in the vesicles and prostate Lidney and bladder as the case may be to be taken care of by reliance upon the im provement in general condition after the removal of the scrotal focus followed by employing hygiene tuberculin or both to immunize the individual against further out breaks of the disease. As has been pointed out tuberculosis of the upper urinary tract may be associated with the genital tubercu losis in some instances and a knowledge of the condition of the bladder and kidneys should be ascertained if possible by cystoscopy ureter catheterization and renal function tests before the method of treatment should be decided upon, and if a complete examination of the upper urinary tract is im possible at least a catheter specimen should be subjected to urmalysis and bicteriological study It is obvious that a complete knowl edge of the individual case 1 of value in prognosis and must influence the course of procedure in the treatment \aturally a patient with tuberculosis of the whole genitounnary tract or advanced phthisis should not be treated surgically except in a pulliative

Before proceeding to elective surgical oper ations upon the genitals it is essential to have besides a complete knowledge of the genito-urnary system the evidence fur inshed by a general physical evanunation for it has been shown that tuberculosis of the urogenital system is always to be considered secondary to a tubercular processelsewhere in the body. It is only upon a complete knowledge of the individual case that appropriate treatment can be instituted.

It must be clear that the problem of treat ment must be considered as one of immunication for with the presence of tubercular foci in different organs of separate so temos the body no surgical procedure can entirely free the patient of the disease as such all evidence in regard to the surgical treatment of tuberculosis points to but one conclusion namely that surgical treatment does not in itself fulfill all the indications and

localized tuberculosis in the genital system as elsewhere should therefore not be con sidered as a purely surgical problem but rather that surgery may be a valuable method of freeing the bodies of accessible foor that the natural immunizing function of the body may be improved and other immunizing measures may be more effective.

In regard to what may be expected from surgery as applied to genital tuberculosis there is no report as complete as that by Barney He has shown from a tudy of 154 cases of genital tuberculosi at the Massa chusetts Ceneral Hospital that tuberculosis was demonstrated chinically in other part of the body in 55 8 per cent of the cases (lungs 35 cases kidney 7 cases bones 7 cases) Of these 134 patient he wa able to truce 113 and found that at died of tuberculosis and 8 from other causes. Of the 31 patients dying of tuberculosi 15 developed signs of tuberculosis elsewhere in the body following operation Of these 31 cases 4 or 142 per cent died in the hospita within a month after operation o or 32 1 per cent died within 6 months and that within one year so per cent had died. At a period of six years after operation 8 per cent had died

The results obtained by the attempt to remove the whole genital tract are not at hand except those of Whiteside's who in 1914 reported 22 cases of removal of the whole or one half of the genital tract that is the testicle with the epididymis the vas seminal vesicles and prostate. In that series he considered 4 cured 9 died or phthias (time after operation not stated). 3 died within a few months from local infection. 6 were lost sight of presumably they may be dead. There was no operative mortality. The time required to do the operation was about three hours.

Personally I have recognized the advantages of a total extirpation of the gental tract in suitable cases because of the associated tubercular lesions in other parts of the gental system yet the technical difficulties entailed in performing this operation several times upon the cadaver have kept me from employing it in the living

The most complete report of cases followed

for many years, that I can find is by Haas. He records the results of the Tuebingen clinic of Bruns, which follows 111 patients, upon whom either single or double castration had been performed were examined at periods subsequent to the operations varying from three to thirty years. In 78 of the cases one testicle, and in 33 of them both testicles were removed. The vas was divided high up in all cases. In 26 per cent only of the unilateral castrations did the disease appear in the other testicle later but 9 per cent of the same patients died of tuberculosis of the urmary tract. Most of the latter number had shown evidence of tuberculous desease of other parts of the tract previous to the operations. Cure followed the unilateral castrations in 44 6 per cent of the cases Of the 33 patients who were submitted to double castration 56 per cent were cured, 156 per cent died within the first three years after ward from genito-urinary tuberculous in some form or other The mortality there fore, of complete custration within the first three years after the operation was nearly twice as great as that seen in connection with the unilateral operation in the same period but, on the other hand, the percentage of cures among the patients upon whom complete castration had been performed and who survived more than three years after ward, was noticeably greater

The procedure of removing the scrotal focus, either by epidelyectomy or exattaken with subsequent hygienic treatment, and in recent years by employing tuberculin is today the most common practice. Barney s report, the most recent and complete in regard to end results, showing a mortality of 85 per cent within say years following such procedures in an institution of the highest surgical efficiency is far from satisfactory

There is much evidence in support of the benefit which may be expected by the employment of hygiene and tuberculin. I have tecently enamined several cases who have been under the care of Dr. George Sanborn, durector of the Department of Vaccane and Serum Therapy at th. Bostom City Hospital. I am convinced that much benefit has resulted in the cases which have been treated

by tuberculin subsequent to the removal of local genital foci and there are two cases with which I have been personally familiar that from all objective and subjective signs may be considered free from tuberculous in the cenito-urinary tract without any previous surgical procedures. One is a young man seen in 1907 by Dr John T Bottomley A diagnosis of tuberculosis of the right kidney was made by ureter catheterization and moculation tests, and there was a characteristic unliateral genital tuberculosis. An abscess developed in the scrotum from which the tubercle bacillus was isolated After 18 months. treatment by tuberculin the symptoms were entirely absent and two years ago 1914 Inoculation tests of the urine were negative.

Another case a man 24 years old had a unilateral genital tuberculosis resulting in abscess formation in the scrotum. After 6 months treatment with tuberculin the wounds were healed and there were no subjective symptoms. This patient was seen on March 26 1016 The testicle and epididymis were practically destroyed leaving a small fibrous body There was a hard nobule in the left lobe of the prostate and the left vesicles had somewhat thickened walls but not enlarged. The material expressed was not abnormal and inoculation tests of the urine were negative, and no organisms could be found in amenra. There are many other cases who have received the same sort of treatment in which the results are not so brilliant, yet I am convinced that this form of treatment is a great adjunct to surgical measures and should form the after treatment in all operative cases and the chief feature in non-operative CASCS.

Being convinced of the greater advantages to be gained by eliminating the dusease from the structures in the genital tract above the epidulyms, and yet being fearful of a radical surgical procedure which attempts to wholly eradicate the disease because of the difficult test dangers and failures. I have chosen to attempt to remove the disease from the vas, vesicles, and possibly the prostate by performing epidulymectomy or extration injecting the vas with crude carbolic acid and later employing hygiene and tuberculid. The

idea of this form of treatment was suggested by Belfield's paper entitled Irrigation and Drainage of the Seminal Ducts and Vesicles Through the Vas Deferens in which he advocated treatment of the infected vesicles by injections through the vas deferens and from the results of the treatment of the tuber cular ureter by the injection of carbolic acid following nephrectomy as practiced at the Mayo Chine.

The number of cases subjected to this method of treatment in which the results are known is 32. In 14 lesions of the epididy mis alone could be demonstrated prior to operation In 18 lesions of the vesicles were present and in 15 lesions of the vesicles and prostate also were evident. In 5 patients the lesions in the epididymis were bilateral Three patients had tuberculosis of the blad der and unilateral renal tuberculo is cases with bilateral renal tuberculosis were subjected to epididymectomy or ca tration and are not considered in this report ty three had phthisis and 2 had tuberculosis of the bone. Thirteen were subjected to unilateral epididymectomy 2 to bilateral epididymectomy i epididymectomy on one side and castration on the other 14 were subjected to unilateral contration because the disease involved the testicle and 2 bilat. eral castration a had a subsequent could be mectomy for recurrent disease, and 4 had a subsequent castration for recurrent disease 1 had a subsequent nephrectomy and 2 had previously had a nephrectomy for tubercu losis I have previously mentioned a case of tubercular epididymitis on one side and a gonorrhœal epididymitis on the other tubercular epididymis which was removed showed both a tubercular and gonorrhoeal infection Of these 32 patients 7 are known to have died The following table shows deaths by year and causes.

Year	Po-t operative	Aurosber of P time	Per	Cent	Remark
rd 1 th	0 Months 0 months 19 Deceths		1		Nervon brakdown Smeath Pott drawse nd ph hass Philhato-multary berculosa
Zila Zila	to months		3		Philipps—uran neg tre
Se h			١ ;		Phehase urms nega ve Fubercul hungs and klipcys

Of this series of 32 patients the urine has recently been studied in 25, these being alive at the present time and no evidence of genital tuberculosis is to be found in 21 tubercular lesions in the bladder and prostate five years after unilateral castration and is one of the cases in which a nephrectomy was done. One has bilateral renal tuberculosis 7 years after operation, and two have tuber cular lesions in the prostate and possibly the vesicles one four years and one three years after operation. Of the remaining 21 cases there is no evidence of the disease in the local examination, the urine is negative, and smears of the massage fluid from the prostate and vesicles is negative in each instance. In but one patient was the inoculation of urine into guinea pigs positive and this case had a right castration in December 1914 and a left February rors. The urine is negative by urinaly is and the smears negative. nationt is in excellent health and the inocula-

tion finding were a surprise

To summarize Of these 32 cases 7 or 217
per cent have died in 10 years 25 or 88 3
per cent are living 4 have demonstrable
tuberculosis in the genity-urinary tract 1 has
no demonstrable tuberculosis but the inocu
lation test is positive 20 or 62 5 per cent are
locally free from the disease

The operative technique is briefly as fol The patient comes to the operation with at least one hour's urine in the bladder or if the bladder is empty about 4 ounces of water is injected. After performing epidi dymectomy or castration the vas is injected with a drachm of crude carbolic acid by means of a syringe fitted with a metal tip usually employed to make injections into a ureter catheter The vas is brought to the surface of the skin through a stab wound above the scrotum and held by a catgut suture the lumen being unobstructed The scrotal wound is closed with or without drainage as the case may indicate and an alcohol dressing applied to neutralize any of the carbolic acid which may escape The urethra is washed out to remove any carbolic acid which may have escaped into it but as a rule the acid runs back into the bladder and is diluted by the bladder fluid

Upon recovering from the operation the nationt usually voids early as the irritation from the carbolic acid is evident, and because the bladder contains fluid at the time of opers tion. In a few instances the patients have required catheterization.

Pain during the first few days after opera tion is often considerable requiring liberal doses of morphia vet some patients have had little or no pain. In a few micturition has been so frequent and painful that an indwelling catheter has been necessary and several patients have passed blood in small amounts, mixed with the unne for a few days to a fortnight. There is rarely vesicle colic" and rectal irritation, and the urine may contain much detritus for many weeks. There has been no evidence of carbone and poison-

The reaction from this method of treat ment, while severe in some cases, is slight or absent in others and whatever immediate discomfort there may be is of only passing interest if we can free the genital tract of so

severe a discase.

The examination of the vesicles and prostate months following operation usually shows the vencles to be small fibrous bodies if palpable at all and the prostate sometimes quite normal but often sclerotic and the material expressed by massage is small in amount. In no instance has the massage fluid following operation shown the tubercle bacillus in smears, and in no instance has a contracture taken place in the urethral canal.

Following the healing of the wound and the subsidence of any febrile state patients have been given inberculin, the dose being at first small and gradually increased The general hygienic measures, commonly employed in tuberculosis, are insisted upon and carned out indefinitely

CONCLUSION

1 The post mortem and clinical findings show that the great majority of cases of genital tuberculosis have active tuberculosis elsewhere in the body the infection in the genito-urmary tuberculosis being a secondary infection

- 2 It must be considered that the majority of cases of tubercular epsdidymits have to berculous of the vendes and prostate on the corresponding side, whether the condition can be demonstrable by physical examination or not
- 3. Cases of genital tuberculous often have associated tuberculous of the bladder and kidney and a cystoscopic examination with catheterization of the ureter should be a rotation procedure in each case before the posalbility of such associated infection can be climinated
- 4. In the opinion of the writer the best treatment for the local condition in most in stances, is to remove the scrotal focus by epididymectomy or castration, and this should be followed by injecting the vas with a drachm of crude carbolic acid, with the hope of cradicating the disease from the genetal
- 5 That the destruction of the local focus by this procedure is but the first step in the process of immunizing the patient against fresh outbreaks of the disease and that hygiene and tuberculin should be made use of indefinitely as they serve further to aid, in a rational way the immunizing power of the body against remaining lesions.

THE TREATMENT OF THE FATTY CAPSULE AND THE URETER IN FOR RENAL TUBERCULOSIS NEPHRECTOXIX

By HERMAN LOLIS KRITSCHMER, M.D., FACS, CO.A. Urologist Presbyteria Hospital Genoto-Union Suracco Mayora B. ht. Hospital Junior Surgeon Child Memoral Hospital

IN a consideration of the surgical treat ment of renal tuberculoss two fact stand out prominently (1) the present status of the question relative to the diagnosis and treatment of renal tuberculo-515 (2) the fact that the management of the fatty capsule and the ureter has not been a definitely settled as has the former

With reference to the first topic I should like to refer to Cabot's introduction to a recent article on this subject in which I think he sums up the question of diagnosis and treatment as well as it can be many points connected with the diagnosis and treatment of renal tuberculosis have been practically settled during the past ten years much still remains to be done. In expert hands the questions of diagnosis have been well cleared up and the formerly much discussed question of the advisability of surgical treatment has ceased to play an important part. The tendency to watchful waiting which was generally but another name for medical procrastination has considerably abated and there is practically no difference of opinion among those qualified to express one that in unilateral renal tuberculosis

Read part of the symposium on Tuberculous of the Kulzu

operation offers the only chance of cure and the so-called medical treatment only prolong the agony

When however our attention is directed to a consideration of the management of the fatty capsule and the ureter in nephrectomy for renal tuberculosis one finds a great many different expressions of opinions somewhit analogous to the unsettled and chaotic condition which the entire question of surgery of kidney tuberculosis was in ten years ago Because of these facts one is justified in tating that the question of treatment of these two tructures is not as definitely settled as are the questions of diagnosis and treatment

Until comparatively recently the fatty capsule has been either ignored or sadly neglected. Many of our trindard textbook do not refer to it at all Just why it hould have been overlooked is not clear. Many of the more recent writers attribute to it the possibility of its being one of the causes of post-operative sinus formation after nephrec tomy and that not all of the post-operative tistule or sinuses are due to the uniteral stump \ consideration of the fatty capsule as a factor in the production of h tula

American Littleane I Association of Lords April ~

or of an infection of the wound by tuberculoas cannot be undertaken without reference to the lymphatics.

The most extensive work on the lymphatics of the kidney and its capsule has been done by Stahr. He has shown that there are two capillary networks within the fatty capsule of the kidney A coarser network which lies under the peritoneum, superficially in the fatty causule. A second capillary network lies in the deeper layers of the fatty capsule close to the kidney substance. This is a delicate network and according to Stahr is in direct communication with the lymph capillaries of the kidney cortex. By injec tion preparations he was able to demonstrate that the kidney possesses a rich network of lymphatics. The different lymphatics leave the kidney at the kilus but in spite of this he has demonstrated that a lymphatic connection exists between the lymphatics of the hidney and its ca esules

These anatomic facts are of much importance in a consideration of the treatment of the fatty capsule. If we accept Stahr's work as having proved that this lymphatic connection exists, then it is reasonable to expect that in all, or in the largest majority of cases, the fatty capsule must sooner or later become infected. The possibility of the fatty capsule becoming infected in each case naturally brings up the question of whether or not it is proper to remove it as a routine

in every case.

Clinical evidence of involvement of the fatty capsule is seen in some of the late cases in which at the time of operation the fatty capsule can be recognized as being definitely pathological. Schlaginweit, in one of his cases found a pathologically altered and enlarged lymph-node about the size of an

almond, in the fatty capsule.

Legueu maintains that the fatty capsule is almost always changed, indurated and more or less adherent to the kidney Sometimes the lesions are purely inflammatory but they are generally tuberculous, and many authors have demonstrated specific lesions in them (Israel Alborran, Pousson Kapsammer Kidd)

Tuberculosis of the fatty capsule may be evident in cases where tuberculous granula

tions are seen on the surface of the kidney Not only are tuberculous changes found in cases in which the fatty capsule appears after ed to the naked eve but they have also been found in cases in which the fatty capsule appeared perfectly normal Legueu has demonstrated microscopic tubercles in the perirenal fat, in preces of the fatty capsule taken at random from areas that appeared normal to the naked eve.

These facts would appear to be rather con clusive evidence in favor of a removal of the perirenal fat, or as much of it as possible in cases of nephrectomy for tuberculosis. Albarran believed that the course of the disease was shortened by secondary removal of the fatty capsule However Schlaginweit, holds opposite views. In his first nine or ten nephrec tomics he removed the fatty capsule with a great deal of trouble and loss of time but since then he has left it in place He believes that if the fatty capsule is normal soft, and does not contain any palpable glands it does not do any harm if it is hard and rigid, it has formed a protective wall before the opera tion and will continue to do so afterward. Recommendations to remove the fatty capsule have been made by Kuester Koenig and Pels Leudsen Kidd Wildbols Kelly Watson and Cunningham, and others.

During the past three years I have made it a routine procedure to remove as much of the fatty capsule as possible. This was carried out after the kidney was removed. In cases in which there has been a good deal of peri nephritis, with extensive thickening of the fatty capsule so that extensive adhesions are present, rendering the removal dangerous it may be necessary to forego its removal The danger of injury to the peritoneum with resulting tuberculous peritonites is obvious

THE TREATMENT OF THE URRITERAL STUMP The management of the ureter has caused more discussion than perhaps any other phase of the subject, and it is the one which up to the present time has not been satisfactorily settled to all concerned. The many different ways of treating the ureter which have been advised is proof that the ideal method has not been obtained.

When nephrectom, was first recommended it was also advised to remove more or less completely the diseased ureter. The more recent train of thought seems to be to re move only a part of the ureter as much as can be conveniently removed through the lumbar incision which usually means to the birm of the pelvis.

Total extirpation of the ureter to the bladder or to include a piece of the bladder was not a very long lived procedure. These proce dures were recommended by Alessandri Gar Giorgano Ramsey Goetzl Kelly Reynolds Israel Kapsammer and others This method soon fell into disfavor because it did not fulfill its claims because of the increased mortality rate and because it did not prevent post-operative fistulæ Although the present-day tendency is not to do cx tensive resections. Longard has described a new technique which has for its object the removal of as much of the ureter as possible

The kidney is exposed by the usual lumbar incision after the vessels have been heated and the kidney freed the ureter is freed down to the pelvis and a second incision is made parallel and close to Poupart's ligament The incision is carried through the muscles to the pentoneum the kidney and the attach ed ureter are pulled through this incision after which the ureter is divided and fixed into the wound. In large kidneys or where there is danger of rupturing large pus-sacs he divides the ureter in the kidney wound covers the end with gauze and then pulls it through the lower incision with a forceps His method slightly modified has been advocated by Lillienthal

Suture of the ureter to the skin This meth od was advised in order that the ureteral mucosa could be treated directly and to prevent infection of the wound with tuberculosis and fi.tula formation Israel in his analysis of 1023 cases obtained figures showing that fistulæ occurred in 10 per cent of cases in which the ureter was fillowed to drop back into the wound was followed by histulæ in 163 per cent of cases.

Treatment of the ureteral mucosa has been varied Kuemmell uses a special thermo-

cautery which is introduced into the urcter and Albarran Tuffier and others sear it with heat Electrolysis has been advised Israel prefers the injections of pure fluid carboine and into the lumen of the ureter filling up the entire ureter and Koenig injects fincture of iodine. In order to bring about an early healing I aschkis advises that the stump begiven antituberculous treatment after the operation. Zuckerkandl recommends 6 per cent carbolic and. The mucoan near the end of the ureter has been removed with a curette. Comment on these varied recommendations is unnecessary.

METHODS OF SEVERING THE URETER

These have been varied. The end of the ureter may be crushed with a heavy forceps and cauterized with carbolic or iodine. Others prefer to burn through the ureter very slowly with the actual cautery.

Inragination of the cut end of the unter by a purse string somewhat similar to the tech inque in appendectomy has been suggested in order to insure a more thorough closure of the cut end either with preliminary crushing of the uncter or with ligating Ligation and invagination have been criticised because the end containing the ligature lies in the lumen of the ureter. This method has been advocated by Koenig Kuester Pels Leusden Krecke Jansen and others.

That occasionally special treatment is not necessary is demonstrated by Schlaginweit. In several cases the ureter was simply cut off and allowed to retract The cases ran a usual post-operative course Taddei has shown by experiments that the ureter closed quicker when it was not ligated When it was ligated hollow spaces formed in the walls resembling true cysts. There was never a trace of reflux of urine into the wound. The ureter atrophied quicker when no ligature was applied therefore in non-septic conditions he advises against ligation of the ureter would not feel justified however to apply the results of Tadders animal experiments in his own clinical cases.

At the present time based upon past ex perience and results by far the largest num ber of surgeons are practicing less radical measures than formerly so that only a partial ureterectomy is carried out.

I have never attempted extensive resections of the ureter being content to remove as much of the ureter as I could through the lumbar wound. Usually I was able to divide the ureter at the pelvic brim, and occasionally just below it. The ureter was divided between heavy artery forceps. The cut end was treated with carbolic acid and tied with heavy catgut, and allowed to drop back into the wound. The objection to leaving a stump of the ureter has been that it continues to pour infectious material into the bladder thereby infecting a clean bladder or delaying the healing of an already infected bladder. Who can say that a long stump is any more infectious than a short one?

Albarran Kuester Koenig and Pels-Luesden Suter Mayo Legueu, Cabot, Sequier Borelius, Kidd, and others are all dong partial ureterectomies. Post mortem examinations of the stump after nephrectomy have shown that the ureter has undergone atrophy and been converted into a hard, fibrous cord

Attempts have been made to modify the technique according to the pathological condition of the preter. Some believing that the technique should be based upon the condition of the ureter as found at the time of operation. As a rule however the condition of the ureter has not been taken into serious consideration.

Albarran s decision whether a conservative or radical preferectomy should be carried out, is reached upon the ureteral findings. If the thickened ureter is increased in circum ference because of a thickening of its walls and if its lumen is small he proceeds as usual in that he resects as much as can easily be resected and these cases heal without fistule formation. If the ureter is very thick, and the lumen on cross section is dilated then and only then should ureterectomy be carried out as completely as possible. In these cases the verical end of the ureter is dilated and altered This is the type he believes, in which the bladder urine flows up the ureter and into the himbar wound

THE INFLUENCE OF EARLY DIAGNOSIS

Tuberculosis of the kidney is no exception to the rule that an early diagnosis is by far better than a late one. From personal observation I believe that cases in which an early diagnosis is made and in whom an early operation is performed have less bladder disturbance after the operation, and that bladder symptoms persist for a much aborter time than they do in those patients who come to us late in the course of the disease.

At rare intervals one may see a case in which there is no evidence of bladder or ureteral tuberculosis cystoscopically. This group of cases undoubtedly have a much better end result than do those in whom at the time of operation an extensive tuberculosis of the bladder exists.

By many these facts are held responsible for fewer ureteral fistula and hence a shorter period of wound healing. One must not forget, however that in renal tuberculosis involvement of the ureter occurs quite early

While many authors believe that fewer post-operative fistules and a shorter wound healing are directly due to an early diagnosis and early operation, these views are not held by all. Some believe that post-operative fistules are not due to any particular type of unretrial tuberculous but to a better operative technique, rigid assepsis and a more careful division of the ureter.

PRIMARY CLOSURE

The formation or occurrence of post operative issules and infection of the wound by tuberculosis has resulted in the various methods of treatment of the ureteral stump and the fatty capsule. The objects of these methods however were not attained. This failure was quite common so that some (Oppel, Sten) did not try to obtain primary wound healing. Instead they packed the wound with gause and allowed it to heal by eranulation.

This technique must of necessity prolong the convilescence and as a routine procedure can hardly be recommended, except in an occasional case in which the wound may have been contaminated by pus due to rupture of one of the thin walled sacs. Quite the opposite treatment has been advocated by Mayo who advises against drainage. In cases in which the wound is soiled by infected material this is wiped out the cavity filled with normal salt solution and the wound closed without drainage. If this method succeeds it will add greatly toward shortening the convales ence

Cabot and Crabtree's interesting study of their cases closed without drainage show that only 25 per cent remained tight. Another fact of much significance brought out in their paper is that in their cases in which an abscess developed it occurred in three to two weeks after the patients left the hospital. This fact is especially significant when reporting cases.

of primary closure unless the cases are watched after leaving the hospital one might easily come to wrong conclusions

REGURGITATION OF URINE

Regurgitation of urne into the remaining urcteral stump and its discharge through the lumbar wound may be the cause of a persistent sinu. Tuberculosi of the urcter often results in a destruction of the urcter overeal valve so that there i nothing to prevent the flow of urne through the lumbar wound. Flu complication however is rare. I have seen it but once. One might be guided in his attempts to prevent this complication by the cy-toscopic findings.

THE CLINICAL AND PATHOLOGICAL EVIDENCES OF THE POSSIBILITIES OF SPONTANEOUS HEALING OF RENAL TUBERCULOSIS WITHOUT TOTAL DESTRUCTION OF THE KIDNEY

Bi FDWARD L YOUNG JR M.D. BOSTON
Gendo-Urmary Surgeon Out P tient Department. Missackwetts General Hospital

N any discussion involving a number of terms which may be used with varying shades of meaning it is only fair that a complete understanding of what we mean by our use of words should be made plain that no doubt or question should arise later

Is evidence of renal tuberculosis we must have tubercle bacilli and evidence of renal inflammation coming from the kidney. It is not enough that these elements come from a bladder umpe since genital tuberculosis in either sex coming from the epididymis or the prostate in the male or from the fallopian tubes in the female give such a urinary con tent it is not enough that the bacilli be found in the uring when obtained direct from the kidney if there is no other evidence of Lidney involvement since it has been proved beyond doubt that normal kidneys excrete hving tubercle bacilli coming to them in the blood from other tuberculous foca in the body in as much as no one will deny the possibility of small active tuberculous foci in the body

which are undiscoverable on physical examination bacilli alone in the urine cannot be accepted as evidence of renal involvement By healing we mean a complete destruction of a tuberculous focus so that no living tubercle bacilli remain. It is not enough that a caseous area is completely surrounded by a wall of fibrous tissue however dense so long as the center is not completely organ ized Kurlow and Green by use of the microscope and guinea pig inoculation proved conclusively that as long as cascation existed there remained the possibility of further in fection. It is true that under the best of artificial conditions a strain of tubercle bacilli will die in a comparatively few weeks but these are not and cannot be the conditions existing in the body and at present we have no means of knowing how long tubercle bacilli in a caseous mass can retain their vitality and power of doing harm. By healing then we mean the destruction of all of the tubercle bacilli and the reduction of the caseous nodule to a harmless condition

By spontaneous healing we mean not only without any treatment at all but by the use of any treatment outside of the knife.

What can we accept as a sufficient proof of a healed renal tuberculosis? Nothing less than the operative or autonay evidence of what we know is a characteristic organized tubercle or collection of tubercles taken from the kidney of an individual who showed dur ing life tubercle bacilli and evidence of renal inflammation coming from that kidney

Clinically there have been many reports of cases of renal tuberculous where the diagnosis was certain and where either without any treatment or because of or coincident with the use of some special therapeutic agent the clinical signs and symptoms entirely disappeared pus and albumin and tubercle bacilli could no longer be found in the urine and the venical symptoms of unitability ceased and the patient gained in weight and general condition.

Pardoe reported 21 cases in which 5 spneared to be cured by the use of tuberculin in very early cases where there was little if any bladder involvement. But recognizing the possibility of long remissions in the signs and symptoms he did not consider proof of

the cure at all complete.

Thompson Walker also considered the use of tuberculin as likely to give freedom from symptoms for a long time but did not believe that a cure ever resulted

Keyes reported three cases before this association in which there was a remission of from 2 to 17 years. In the case with remission for the longest time the diseased kidney was entirely destroyed as proved at autopsy In the other two there was a flare up of the disease and nephrectomy was done

Heatz Boyer reports one case in which there was no suspicion of tuberculosis in the history physical examination, or cystoscopy examination two months later showed a closed left kidney which had not been diagnosed on the heat examination A few months later the patient died of uremia

He cites another case in which a patient was supposed to have been cured of renal tuberculosis, but twelve years later had a swelling in her loin which did not interfere

with her general health and activities so that she did not consult with a physician for eight years more. A nephrectomy done at that time showed a totally destroyed easeons

Mantoux advocated the use of tuberculin in renal tuberculosis and claimed that the general health was much improved and also that the local condition was changed for the better and although among seventy cases which he observed some were at one time or other almost free from symptoms, he never theless did not claim a cure by means of medical treatment and insisted that operation gave the only chance

Le Clerc Dandoy adopted Acersmacecker's method of administering tuberculin treat ment which consists in giving intravenous injections of connamylic acid every week. increasing the dose up to 20 mg. At the end of six months thus is stopped and the tuberculin is given in slowly ascending doses. He reports five cases in which a diagnosis of renal tuberculosis was made and in which after several months treatment by the mixed method the symptoms entirely deared in and the urine became entirely normal. Two of the five cases give all of the symptoms necessary to make a diagnosis, but the final proof of cure is lacking

Pousson has reported one case with re mission of symptoms for eighteen years and then further trouble and he has become reluctantly convinced that renal tuberculosis cannot be cured except by removing the

kldnev

None of the reported cases on close exam ination fulfil all of the requirements necessary to establish definitely the proof of a cure and many of them do not have all of the data possible to obtain during life. The cases reported by Keyes showed at one time all of the clinical phenomena consistent with a cure and had the final flare ups not been reported would have been used as evidence of a cure instead of standing as they do as strong arguments against. In the literature on renal tuberculosis I have not been able to find any case reported which shows positive proof of the disappearance of a renal tuberculous

The following reports of cases studied on the Gento-Unnary Service at the Massa chusetts General Hospital are of considerable interest in this connection.

G U Service No 03058 Female age 31.

Symptoms of intermittent pain in left side for three months no other symptoms and well up to that time. The utine showed a moderate number of leucocytes no albumn, no growth on culture but a diphtheroid bacillus in smear Cystoscopy showed that the leucocytes came from the left Eldney Operation by Dr Cabot showed that the upper pole contained a cyst shut off from the pelvis of the kidney. The upper pole was resected under the impression that it was a solitary cyst no suspection of its nature being entertained Normal convalescence. The diagnosis was only revealed by the pathologist

G U Service No 20473 Female age 48 ness slowly increasing with an ache in the left flank. The examination was typical of a coccus infection of the left kidney with perinephritic aboses. Operation showed this condition and because the kidney was badly damaged it was removed. Jathological examination showed the corcus infection but in the upper pole was a small caseous cavity.

partly organized which was tuberculous
G U Service No 180035 Female age 54

Five years ago urgency and frequency and three years ago tumor in left flank. Apphrotomy was done at this time. Sinus persisted and two years ago an attempt was made to cure this by operation without success. Apphrectomy was done

Pathological report Section showed no kid ney substance A number of small abscesses filled with thick pus but a large amount of the tissue consists of soft yellownsh material Microscopical examination shows the kidney tissue replaced by a round and epitheliond cell growth throughout which were masses of large scattered giant cells.

In these cases there was a shut off tuberculous process which it was impossible to diagnose as such without microscopic study but in one no evidence at all of any attempt at healing in one only a slight attempt while in the third a considerable degree had gone on, yet in no sense of the word to completion.

Pathological evidence at our command is unfavorable to the possibility of the healing of tuberculosis of the kidney. Wherever tubercle bacilli lodge and start to develop they arouse a reaction which is essentially the same under all conditions the particular tissue invaded causing only minor differences. The process of growth and attempt of the tissue at walling off and healing the damage is likewise essentially the same. Histologically the process is in brief as follows. The pre-

ence of the bacilli is the signal for an ac cumulation of endothelial cells around them in an attempt to neutralize in some way the damage being done These endothelial cells together with lymphocytes and new con nective tissue cells gradually get more numerous and the shutting off of the blood supply begins in the center of the tubercle. If healing is to take place the newly formed con nective tissue cells grow into this necrotic center and gradually absorb and take the place of it. There may be a hyaline degenera tion of this ingrowth but the round cell in tiltration and the more or less characteristic center always remain to mark the spot the larger tubercles the caseous center may be replaced by a calculcation surrounded by a dense fibrous wall. This picture is char acteristic and can be distinguished from the scars in the kidneys of various origin which masquerade in the literature as healed tuber Both types are found in the foci of healed or obsolete tuberculosis elsewhere in the body. That this is the natural process which should take place in the kidneys we know from a few reported cases where such an attempt has been made but without suc-

Harbitz reports a number of autopsy and post-operative cases where the tuberculous process had disappeared after complete de struction (autonephrectomy) of the kidney but one case of particular interest

A woman age 33 with symptoms of right-aided kidney trouble for two years. Tuberculous could not be found. Nephrotomy showed nothing wrong but the wound left a persutent sinus. Three months later aephrectomy. Macroscopically no evidence of tuberculosis, but microscopically there are typical tubercles some of which have gone on to almost complete organization but some of which still are active.

Wildbolz recognizing that a marked im provement in general condition followed the use of tuberculin in many cases thought that a corresponding healing might take place in the infected kidney. In four cases he used tuberculin for 2 to 12 months before operation with improvement in general health and with some benefit as regards symptoms. He did a nephrectomy in all of these cases and examined the kidneys care

fully to see what, if any healing had taken place. Nowhere was be able to find any evidence of any process which suggested an attempt at healing. He concluded that although medical treatment might improve the general condition of a patient with renal tuberculouss it did not in the least help the local lesion and that removal of the kidney was the only permanent cure.

Zuckerkandl in discussing the possibility of the shut off tuberculous pyonephrous also describes the indurated tuberculous kidney where the tusue reaction has resulted in a partial healing of many of the foct with a marked fibrous tissue reaction around the tubercles and a acterotic condition of the whole kidney with a thinning of the cortex and a hardening of the parenchyma. In one case which he describes there was also a fatty infiltration of the tissue near the pelvis. But in all of the cases there were demonstrated one or more small active foci. It is to be noted that this process is destructive of the kidney and not healing Zukerkandi con induration of a tuberculous cludes that kidney and hardening of the parenchyma may be taken as a local recovery but never absolute. (One might suggest that this type of healing is not of advantage to the kidney) The diseased kidney even after complete induration is always a present menace to the other kidney and its removal is urgently recommended

Reasoning from still another point of view suggests that healing should be a difficult if not an impossible task Immunity is aroused very slowly in the body by a focus of tuberculors anywhere. In the lungs where the anatomy is such that the growth may be very slow in extension and yet the blood supply so abundant that the toxines are rapidly absorbed and disseminated and the greatest opportunity given for antibodies to be formed such an immunity is often aroused and the process limited walled off and finally healed before it has become too large to handle. In the kidneys the conditions are slightly dif ferent in that extension takes place more rapidly and the antibodies are formed less quickly By the time these antibodies have been formed to any great extent the focus is so large that the most that can be accomplished at the welling off of the process with out complete healing. Whether this is the eract explanation or not really matters little but I am convinced that the question of immunity is the real answer to the problem. In reviewing the course of the patients on whom nephrectomy for tuberculosis had been done at the Massachusetts General Hospital Crabtree and Cabot found that the cases which had done the worst were the early cases those in other worst who had not had time to arouse an immunity. Other reports from other clinics revealed the same thing

I had one experience of this kind which illustrates this condition

A boy of 18 came for slight frequency. His urine was clear but contamed a slight trace of albumin. Cystoscopy howed light reddening around one ureter and on the strength of that he was sent int the house for f riher tudy. When he came in a short time afterward I was unable to confirm the diagnosis. The bladder was entirely normal. The function of both kidneys was equal. The urine from both kidneys was dear and spark ling There were no pus-cells from either side. There was the alightest possible trace of albumin from the supposedly affected kidney Guinea nig inoculation on this occasion showed no tuberculosis I watched him very carefully during the following year At one time a pig was reported positive from the sound side. He finally developed clear cut signs of renal t berealous and I did a nephrectomy. He went steadily down bill from the first with what was apparently a generalised tuberculosis. The kildney boxed a tuberculous abscess in one pole without the alightest attempt at bealing.

Corbus in a paper before this association in which he dealt with the question of im municing potients before operation makes out a good case on the grounds of preventing a rapid dissemination of tuberculous from the stirring up of the operation. Many other authorities have advocated a preliminary tuberculin treatment. If we revenue this evidence we find in it a very strong suggestion that there is no process going on in the body in this disease which has any marked tendency to cause healing or else the immunising pro-This seems to cess would not be necessary me to be the keystone to the whole question If a person has a strong natural immunity to start with an initial infection will not gain a foothold If a process does start in the kid

net the slow course of the formation of antibodies in comparison with the spread of the lesion allows the disease to get beyond the point where it can be entirely obliterated although it can often be walled off so efficiently that the symptoms cease and the condition becomes latent but capable of further mischief if for any reason it gets loose

It would seem to me from a study of the cases reported in the literature from pathological study and from reasoning in connect tion with immunization that the healing of a tuberculous focus in the kidney is impossible.

OBSERVATION ON ONE HUNDRED AND THIRTY-THREE CASES OF GALL-BLADDER SURGERY WITH ESPECIAL REFERENCE TO THE POST-OPERATIVE TREATVIENT

By R. J. RHODES, V.B. M.D. At LETA, CEOR IV. From he Jeff. as Hospital Rolleck, Verna

THE cases reported in this paper were patients in the Jefferson Hospital prior to July 1 1915 and were oper ated upon by Drs Hugh H Trout and R L Rhodes. As this article is chiefly a post-operative study lues malignances deaths and of course non-operative cases are excluded. Though the number is small the value of hexamethylenetetramine seems optonounced that it was thought appropriate to publish the results in order to stimulate a further study in other and larger chinics.

Of the 133 cases 32 were male and 101 female Of the 32 males 18 suffered from cholecystuts 6 acute and 12 chronic and 14 had stones Of the 101 women 22 suffered from cholecystuts 1 acute and 21 chronic while 70 had stones Thus in men 43 75 per

cent showed gall stones whereas in women practically 79 per cent Concerning the location of the stones 31 or 34 8 per cent were in the gall bladder alone 22 or 23 6 per cent in the gall bladder and cystic duct 7 or 75 per cent in the gall bladder and common duct 7 or 75 per cent in the cystic duct alone 3 or 32 per cent in the common duct alone 2 or 2 per cent in the cystic alone and common ducts and 1 or 1 per cent stones were found in the gall bladder cystic and common ducts. It is odd that in none of these were stones found in the hepatic duct yet since July 1 three such cases have been en countered.

In women we had 56 cases under 40 years of age and 45 cases more than 40 in men 9 under and 23 more than 40 vears of age. The table of ages according to decades follows

thologic in 34 per cent which includes es showing even a trace of albumin or hyaline casts in other words anything absolutely normal There were heart in only 15 per cent, including all n other than absolutely normal the it lesion being the Adams-Stokes syn

s in only 485 per cent. The unne

in a man 76 years old. case is worthy of detailed report be

of the unusual clinical history brought his son to the hospital ppendix. The father obtained

n acute a home in which there was case of typhoid During his stay in town the father con-us, giving a history suggesting a chroni-stitis over a period of about four years. On I examination this was confirmed and such osis given He took his son home on the with a very acute cholecystiths and t on the gall-bladder was found distended t the point f rupture. Cultures from the s of the gall-bladder yielded a pure culture llus typhorus. H rapidly improved, the sture was normal on the fourth day but to rise again on the sixth day and con through a very typical typhold fever, blood and Widal both being positive. In the week of his typhold he developed a large

al baces which when opened rielded typhosus in pure culture following this, valescence was uninterrupted. point of interest here is the very assumption that, having a chronic low grade cholecystitis, he fell a victum to poor prophylactic precautions in the boarding house and developed the disease, and as the resistance of the gall bladder was already lowered the acute infection manifested itself there before it became systemic,

There were a cases in which the gall-bladder gave symptoms during the course of typhoid fever all of which came to operation with an acute cholecystitis in less than three months time. The operation consisted in the removal of stones where present and the drainage of the gall bladder by means of a large rubber tube introduced into the gall bladder and anchored with chromic catgut. The opening in the gall bladder was closed with a pursestring suture of chromic catgut, care being taken to invert the edges. Two or three

cigarette drains were placed below and around

the gall bladder Post-operative treatment. The patients are placed in bed in the prone position and ordered to have nothing by mouth. Proctoc lysis by the Lawson method is given-water dextrase or sodium bicarbonate, either or in combanation as indicated—and morphia er 1/2. hypodermically every 3 hours, if necessary Water is usually not allowed by mouth within 24 hours if there has been any appreciable nausea and is withheld longer if much nausea or vomiting exists. Gastric lavage if in dicated

In this series of cases the above outline constituted the basis of the routine treat ment in 77 cases in which the average dura tion of drainage was 35 days. In 56 cases in which the average duration of drainage was 203/ days - a difference of over six and one half days - the same treatment was used and in addition hexamethylenetetramine in doses of 50 to 80 grains daily. In cases in which much pus was present at operation the character of the discharge cleared up more promptly in those getting hexamethylenetetramine. For example

A male, age sixty two chronic cholecystitis with subscute flare-up. In spite of free drainage he continued to run temperature daily of co to 1 until the tenth day when he was given large doses of hexamethylenetetramine. In two days it was normal and remained so throughout the rest of his stay in the hospital.

In none of these cases has there been any trouble referable to the gall bladder but among those who were not given hexamethy lenetetramine several have had some trouble

One male age sixty had a cystic and common duct stone with a chronic cholecysitis which drained for 14 days. He returned to the hospital two months later with the history that his gall bladder had drained intermittently for five weeks. When not draining he would have attacks of pain nausea and vomiting such as before operation During the last three weeks three had been no drainage and he had had hive attacks. He was given hexamethylenetetramine in fifteen grain doese four times daily since which his symptoms have disappeared.

Another case a female age 24 had stones in the gall bladder and cystic duct which were drained for 18 days when she left the hospital apparently all right. Four and a half months later she returned to the hospital having had attacks of pain nausea and vomiting as before operation. She was given to grains of hexamethylenetetramine every four hours with prompt relief and has had no further trouble. Another case a female age 21 had stones in the gall bladder and an acute cholecystitis. On sixth day after operation her temperature ran up The wound drained thick mucopurulent material Hexamethylenetetramine as begun and two days later the temperature began falling character of discharge improved until on the eleventh day the temperature was normal and bile drainage with very little pus in it. Further convales ence was uneventful

In making this comparative study no attempt was made to elect the cases but for the most part they were taken alternately with and without hexamethylenetetramine. The larger number without is due to the lact that those having been in the ho pital before

the study was begun are included because the difference in drainage time is so marked it was thought best to get as large a number a possible for an average drainage time

Even though the series i mall it would seem beyond the realm of coincidence that those getting hexamethylenetetramine, hould have an average drainage of 6 days less and when it is noted that the character of drainage imprives 1a ter and that the end results are more satisfactory masmuch as not one who were given it have had any improvementable to the gall bladder after leaving, the hospital—as contrasted with at least four among those who did not—it would certainly seem that the use of hexamethylene tetramine would be a valuable adjunct to our post operative treatment in less ns of the gall bladder and duct.

It is possible to that the indication is richolect tectoms may be lessened especially is this ugge tive in that there were several of the mulberry type gall bladder in the series who were given hexamethylenetictra mine, and who have obtained perfect reher

Note — During the first few day foll wing operation hexamethylenetetramine is given by proceed to 1 because at first the patient are not allowed that by mouth and later to avoid any possibility true time, the stomach. After the first we kill given by mouth. The idea has been to give the drug mye days each week and muttor two day to prevent any untoward ymptom. However should these develop earlier it is stopped for a day of two and then begun a lan.

PRELIMINARY HEMOSTASIS IN GOITER OPERATIONS

BY DR. F DE QUERVAIN BARRI, SWITTERS AND Professor of Chester Surgery

OITER operations are based on one of two principles either the surgeon follows no special plan, excising the goiter as he would any other tumor and ligating the blood vessels as they bleed or he follows methodically a definite plan based on the snatomy of the thyroid gland. The first mentioned procedure precionmated in the early days of golter surgery for the past 30 years, however the methodical plan has been recognized as the only correct one

Though most surgeons of the present day follow the second plan their methods in operating still differ materially. Some show atavistic leanings toward the older method. It is true, they expose the gotter according to rule free it from its surrounding tissues, and lurrate it, clamping and ligating the vessels when blood flows. Others proceed more logically. The genter once delivered the arteness are ligated successively as it is the area supplied by the arteries from which the principal hæmorrhage may be expected. With this step it seemed the summit of logical operating had been attained. Yet it was not so.

Let us follow an operation on an exceeding ly vascular golter with strongly developed capsular veins. We find that the shelling out of the diseased gland from its enveloping thyroid fascia the so-called external capsule and its dislocation can sometimes be an excessively sangulnary proceeding. If then, we apply ligatures to the most important arteries after luxating the goiter we apply them too late for one of the most sanguinary stages of the operation. Therefore we see that to be really logical we should ligate the principal blood-vessels before shelling out and luxating the golter This line of reasoning led me five years ago to modify my operative technique which coincided with that of Kocher and to develop a method which would em phasize the principle of preliminary ligation more forcibly than had hitherto been the case. The chief point in question was the ligation of the most important arteries before doing anything whatever to the goiter. In ad dition to the above mentioned motive of exposing and luxating the goiter with decreased hemorrhage a further consideration presented itself via that the delivery of a profound, intrathorace, richly vascularized gotter is much easier after the circulation has been interrupted than when blood is couraing through the blood vessels. Further my method protected the recurrent laryngean nerves more efficiently than the technique heretolore used and the same time preserved the barathyroid elandules.

I described my method first in December 1911 and then more full, in the spring of 1921. After these few introductor, remarks, I shall describe breaky how the different at tenes can be higated. We will begin with the arteria themsolder inferior. As I explained in my previous paper, this artery is, as a rule the chief source of blood supply to the goiter. Formerly, but quite wrongh, its ligation was supposed to be difficult. A glance at the accompanying schematic sketch (Fig. 1) will show us that this artery can be ligated at four different points.

a Billroth tied the artery quite close to the gotter. Until recently Halsted ligated it at its entrance to or to be more exact, within the golter (ultraligation). In our publication of 1912 we pointed out the disad vantages of his procedure and see with pleasure that Halsted himself has recognized our reasons, and that from his paper of 1917 he has given up ultraligation. We feel gratified that our views now concide with those of an American surgeon who has probably contributed more than any other of his compatroets to the investigation and promotion of the anatomy of the golter and the

thyroid gland.

b. Kocher's method is much more expedient, as it secures greater protection for the

IT IS IMPORTANT that physicians and surgeons should know that it is no longer necessary for those suffering from

Infantıle Paralysıs

to be weighted down with a heavy brace made of steel. It Means Success and Rebulation to you to know where to secure for your patient the proper mechanical appliances which are light enough not to be a detrument and yet strong enough to and t those suffering from any deficiencies in body or limbs. We believe we are the first, and so far the only Manufacturers of Orthopedic Apparatus in this country to introduce and use the metal known as Dwed win which has sufficient tensile trength to insure efficiency in the ppliance made of it and yet the weight is b t one-third that of a similar appliance made of steel We shall exhibit t the Clinical Congress t be beld in this city in October a brace (Int stille

Paralysis mad of Dural min in our own factory by our skilled attrans - pd we can show you, in our est blishment, the raw material, as well as various finished DOMESTIC U.

Hessing's Spinal Corset

An e cellent appliance t benefit those suffering f om spinal irregularities - the aggravated cases where other braces would faul. One of these Cornets will be on exhibition.

By diligence and close attention to the desires of the profession, whose valuable suggestions we are ever ready to adopt, we have become the Recognised Lectors in the manufacture of

Orthopedic Apparatus

W have constructed appliances for many of the leading specialists in this line of work. Our constant study of orthopetic ork through umber of years has made us familiar with the requireof years has made as familiar with the reduced ments of the profession and all ppliances are constructed in our own factory here we have start to finish, thus sensing the physician of the surgeon neatly made and antifactory poli-ances, which will redound it their credit through the appreciation and gratitude of their patients At your request, we will gladly send you cut

alogue illustrating and describing every kind of Orthopedic Appliance of known merit and giving full directions for the taking of measurements which will enable us t mak perfectly fitting appliance on receiving an order by mail from any section of the country

W hope you ill not fail to at ou exhibit t the Clinical Congress and camerily desire to have you wait our establishment. W re sure you ill find there much of interest t you, as you will ace all that is latest in the way of instruments and poliances used in all kinds of surrical work.

hitherto obtained and still obtained by Kocher and many other surgeons by means of this method prove that with sufficient practice the above mentioned structures may be protected with a good degree of certainty Still one disadvantage remains viz. In order to reach the artery the operator must perie trate the space containing the most vena consequently there is risk of extensive venous hemorrhage before reaching the artery especially in the case of neily viscoularized goiters, and more particularly in the case of traves disease.

c. Surely then it must be more advan tageous to ligate the artery somewhat farther away from the goiter in the space containing the small thyroid muscles, outside the thyroid fasca. (the so-called external capsule of the goiter) This is the method we have employed since 1911 Later on we shall describe it more fully

d. Finally we can ligate the ascending branch of the artery as Dietrich first and

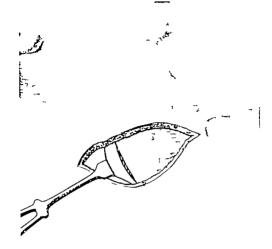

later Langenbeck seem to have done, on the outward side of the carotid artery end Langenbeck incised transversely the sternomastoid muscle whereas Drobnik. taking into account the remonal anatomy proposed penetrating laterally from the out side border of the above named muscle a proposal adopted again later (25 years ago) by Billroth Rydygier and Woelfler also by Reverdin and recently by Alamartine and Rogers. It is clear that in proceeding thus the surgeon intervenes at quite an unnecessary distance from the field of the operation. Moreover as far back as 1801 Woelfler drew attention to the fact that this method is conducive to lemons of the sympathetic nerves. Old as it is, it does not seem to have found its way into the practice of golder surgery and Alamartine a most recent recommendations of it are based only on anatomical considerations. Rogers only has employed it in 37 of his cases

The foregoing demonstrates that we prefer ligating in the space between the outer plane of the thyrold fascia and the inner side of the carotid artery

Before entering into further details we must say a few words about the spaces and fascler round about the thyroid gland. By means of gelatine injections we have in various ways investigated the thyroid region in cadavers. Mr. E. C. Jones translated in this journal a summary of these investigations from our article mentioned above. It was however unduly ascribed to Poulsen whom Jones mentioned on account of his investigations of the other fascue of the neck but who has never examined the spaces round about the thyroid gland.

Our method of procedure was as follows We injected differently colored gelatine into the vanous interstices round about the thy road gland of the cadayer. A transverse cut through the neck after the injected mass had hardened showed us the extension of the different spaces now filled out with gelatine. We devoted another series of experiments to the special study of the fascle, proceeding as follows. We injected completely transparent gelatine under high pressure into all the

At fac cas secretars

Fg 3 Skin a d platysma incised. Muscl at modeldoma tod us tracted outward. The ternal fascia of the small muscles—ve tually in ised—er the sternohyoid must

spaces. We then excised a transverse sec tion 25 centimeters thick from the neck ixed it in Kaiserling's solution and embedded t in transparent gelatine Thus we obtained excellent preparations which had so to say been artificially rendered cedematous to such a high degree that the course of the fascine could be traced into their very finest layers The arteries of these preparations were filled at the same time with red and the veins with the blue gelatine. The anatomical conditions found were the following (Fig. 1) The thyroid gland is enveloped in a thick

layer of its own fibrous tissue called the capsula propria (according to Kocher, the epiths roideum) This fibrous envelope cannot be detached from the thyroid gland as for in stance the fibrous capsule can be detached from the kidney or to be more exact it forms an integral part of the gland. The thyroid gland is surrounded by a space containing fine layers of connective tissue and veins. This space into which only a liquid mass can be injected 1 called the spatium thereoideum. In front it is bounded by a layer of fascia viz the inner fascia of the sternohyoid muscle which more laterally forms the median boundary of the blood vessel sheath Wc adopt for it the same name as Corning and other anatomists, the thyroid fascia It corresponds with what is generally called the external capsule More postenorly this fascia separates into single lamelle which take their way to the trachea, the esophagus and the spinal column Around the thyroid fascia we find another space containing muscles viz the sternothyroideus the sternohy ordeus and a portion of the omohyordeus We call it the spatium sternohvoideum Its outer wall consist of a strong fascia viz

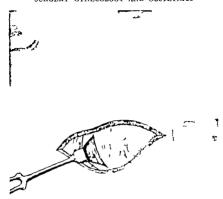

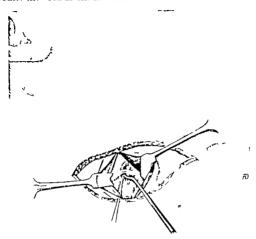

Fig. 4. Small retractor in position. Sternohyoid muscle exposed. The forefinger will now be deeply instinated in median direction t seek and expose the inferior through artern.

the outer fascial covering of the stern hyoid muscle As such it overlays the thyroid region stretching from there to the rear On the outer side of this space we have finally the space containing the sternomastold muscle the spatium sternomastoideum. The blood vessel sheath lies to the rear of the spatium thyreoideum and the spatium sternohyoideum The chief component of its median wall is the fascia thyroidea its anterior outer wall being formed by the fascia ther obvoidea Behind the blood vessel sheath and anteriorly from the profound neck fascia the inferior thyrold artery takes its upward course penetrating the posterior portion of the thyrold tascus on the median side of the caroud artery The parathyroids and the recurrents - the latter within the neld of operation -- are both situated in the spatium thyreoideum. For that reason and because

it contains numerous capsular veins we avon the spatium thyrecodeum as an entry to th arteria thyreoidea inferior Therefore w have at our disposal only the spatium stemo mastoideum. The last named space starting from the median border of the sternomastol muscle is the one which has since the time of Velneau Farabocuf and Kocher beer noted in surgical textbooks as the best entrfor the application of an isolated ligature to the inferior thyroid artery. The operato frees the median border of the sternomastore muscle and then penetrates between it and the fascia of the sternohyoideus. Certainly the artery sought for can be reached in this way but the jugular vein is always reached fire and is hable to injury if great precaution is not exercised. The following course which we proposed for the first time in 1911 is there fort very much to be preferred.

A larger sized retractor has now been inserted. The inferior thyroid arters ha been bluntly drangaged from t urroundings and will be be ligated

We employ Kocher's collar incision divid ing at one sweep the skin subcutaneous fat and platysma myoides. After ligating the superficial veins we free the median border of the sternocleidomastoideus and draw it so far outward with a blunt retractor that the surface of the anterior fascia of the small muscles becomes visible. We then make a vertical slit of about 25 to 3 centimeters long in the latter mentioned fascia (Fig. 3) pare it back bluntly and catch it up with the retractor (Fig. 4) We now work bluntly with a tinger insinuating it deeply in a median di rection along the median side of the common This artery we release from its me dian surroundings and come into touch al most immediately with the arteria thyreoidea inferior which passes at a right angle to and underneath the carotid artery in a median di rection (Fig 5) If necessary we now re place the retractors by others reaching some

what deeper so us to bring the artery into view and with the aid of two long blunt dissectors 17 centimeters in length (Fig. 2) separate and ruse it from the deep neck fascia with a narrow elevator we have had made especially for the purpose (Fig.) The ligature thread is now slipped round the artery with an especially lightly constructed Cooper's needle. In simple cases the whole proceeding from the skin-cut to the tying of the ligature does not take more than a few minutes.1

As a rule no vein whatever except one or two surface veins interferes with the application of the ligature In other cases the vena thyreoidea media crosses the arteria thyreoidea inferior. However, the operator is rarely obliged to ligate the vein in order to gun access to the artery

briefly t anslated from my paper at by E O Jones

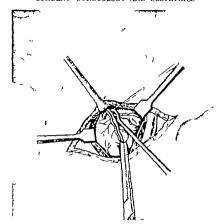

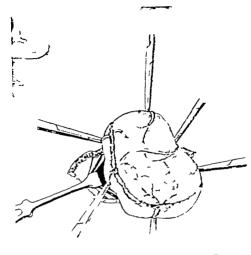

Fig. 6. Spatism stemoty-orients a discreted and a see in now obtained comewhat more medically through the small movels and the thy-rood facts inmedicated in fact of the thy-rood gland (in the spatism thy-roodcum). The gotter is retracted does and before lowering t, in order t light the superior thyroid artery or t innot branch.

The ligature applied, the question arises at the whether the gotter itself requires surgical treatment. If so we leave our space work our way in between the small muscles (Fig. 7) free the gotter whose capsular venus now hardly bleed at all luxate the gotter and undertake whatever the existing circum stances demand excision, resection or enu cleation as shown in the accompanying illustration (Figs. 7 to 9)

The inferior thyroid artery being as we know somewhat less regularly existent than the superior and its course also less regular was as ourselves how often the ligature can be applied in the above-described manner During the first period in which weoperated on these lines, it was possible in 89 out of a hundred cases. In a later series we met with no obstacle in 90 out of a hundred cases.

In only 5 cases wa the ligature impossible owing to the non-existence of the inferior thyroidartery or to its too profound situation

The only real difficulties in the way of applying the ligature in the above-described manner occur when for instance the artery is situated too far thoraxward, or is too far overlapped by the gotter. In most cases the two obstacles may be overcome by using ufficiently long uitably constructed retractors Sometimes the operator is sur prised during the subsequent goiter operation by an unexpectedly strong hæmorrhage after having as he supposes accurately li gated the artery. The reason of this is generally that the ligature has only been applied to the super, r branch of an inferior thyroid artery which divides abnormally near to its origin. In reality this occurs

Fu t la e Chepen

much le trequently than certain anatomi al inve timati n. w ulll ad u to expect

One condition demand attention a it may lead to most unpleasant result to in tan e it may happen that when the urein about thip the Caper needle around an inadequately separated artery has madvertently ued the ligature too tightly a brittle vessel tear or is cut through and it is not alway easy to I hate the ve sel again. This of course is more likely to occur in the case of lifer person, or persons with traves disease. These uni riunate cir. umstance may all be ay ided by arefully 14 lating the arters with two blunt in sector and the narrow elevatir and by nit drawing the liature thread too tightly. In the ale t brittle arteries it L advi able t empl v trong catgut

Of the ogitter we sperated upon it in the beginning of July fort until the end of August 191 we had the apportunity of examining at a later date of assess and epecially assertaining the exact condition in the yield chard. Amon, the 19 cases operated on according to my method comprising of heatures of the interior artery.

nly r ase of permanent paralyst of the recurrent nerve had occurred and that not in insequence to the limature but of the limatic act to between which and the timin and all entropy and the son, had to be

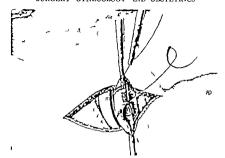

Fig. 8. Gotter removed by means of resection enveloping or combination of both. The largest velops and the anterior branch of the superior thyroid rivey are ligated. The smaller edge have been drawn into the hermost the suture. A lobe of almost normal size has been formed out of the remaining gload tissue.

severed. Two further cases of permanent naralysis of the vocal chords occurred after operations on the old lines (intrafascial ligation of the artery) In 8 cases we found paresis such as any method may occasion through stretching of the nerve during the process of luxuting the goiter. All these 8 cases of paresis were on their way to recovery The cause of these paretic conditions was not always to be determined with any amount of certainty Particulars of the cases will be found in my recent paper and in that of my assistant, Dr Hoesaly in the Deutsche Zeitschrift fuer Chirurgie December 1015 The chief point is that among 250 gorter operations only 3 cases of permanent insure to the recurrent nerve occurred, and that of these 3 only 1 occurred among the 107 cases operated on with the new method.

tected. The thorough investigations, notably of Erdhem, Halvted Geis Evans, Bérard, Alamarune and Ivenen, with regard to the blood supply of these organs, prove that each of them is supplied by a fine branch of the artern thyreoldea inferior or by the branch artery connecting the inferior with the arteria

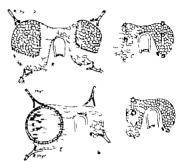

Secondly the parathyroids must be pro-

thyreoidea superior \ little simple reasoning will make it clear that this fine blood supply can most effectually be protected by ligating the large arterial trunks as far away from it as possible. This course alone insures the safety of the fine arterize parathyreoideze during the operation and provides as large a field as possible for the collateral circulation Therefore the farther away from the thyrold gland a ligature is applied to the inferior thyroid artery the less the danger of injury to the parathyroids. For the past five years I have advocated this principle and am glad to see that it is becoming more and more recognized Up to the present I have in more than 200 cases tied both the inferior thyroid arteries at one sitting and have never seen a trace of tetany Neither have I found this condition in the numerous cases. in which I have simultaneously ligated three arteries, or when ligating the two inferiors, one superior and the front branch of the other superior thyroid artery. We can therefore say that tetany is not the result of the lighture itself but the result of a high ture improperly applied.

The third organ demanding protection is

the sympathetic nerve. Hitherto it has received but little attention and many surgeons have severed it with therapeutic intent in cases of Graves disease without considering the far from pleasant consequences of a sympathetic paralysis especially the consequences of a sympathetic ptosis and miosis Just the last named symptoms demonstrate the desirability of shielding the sympathicus especially when Graves disease is not the cause of the gotter. In such cases nothing could justify a lesion to the nerve. Our in vestigations show that the sympathetic nerve is somewhat more endangered by our method of ligation than by the older method tainly more exact investigations on injuries to the sympathetic nerve in the course of other methods of goiter operation are lacking It is principally in danger of being crushed by the retractor used to draw the carotid out Among the 250 cases we subsequently examined there was only one of decided sympa thetic paralysis and three with slight pareses In several cases the nerve was defective before the operation. These figures show that the danger is not great At my request Professor Metzner and Dr Woelfflin have investigated the sensibility of the sympathetic nerve with regard to traumatic lesions and have found that in the case of rabbits a traction of 10 grams a minute is the maximum that can be endured without a reaction on the part of the nerve An increase in weight of 1, to 20 grams produced regularly vascular and ocular pupillary symptoms the latter of which completely disappeared in only a few Still in order to reduce even this slight danger I have constructed the retractor I employ for drawing outward the carotid ar tery in such a manner that it does not rest on the vertebral column with a long edge but with only two supporting knobs risk of nerve lesion is but slight (Fig. 2 1)

We will now proceed to the ligation of the arteria thyreoidea superior. On this point there exists less difference of opinion therefore will also treat it briefly one of the superiors is to be ligated it can be done from a short transverse cut made pre cisely in the line of the skin folds at a level with the thyroid cartilage. If the two supe

Pla or the go ter operation f both lobes B on sided on a leation R recurrent erve E epithelial bodies

mors are to be occluded a corresponding cut is made on the other side and the operation carried out in the same manner whether it be a question of pure arterial or pole ligation If however in addition to the superiors the inferiors and the goiter itself are to be in luded in the operation all can be done as Tayel was the first to prove ligation of superior and interior arteries lobectomy etc from the usual collar incision. The entry this incision provides is ample for the ligation of the uperiors it only the upper skin flap is drawn sufficiently high upward and the small muscles retracted outward and up ward (Fig. 6) As a rule it is quite unneces sary to luxate the gotter before applying the ligatures On the contrary we generally ligate the superior thyroid arteries before dislocating the goiter whether we restrict ourselves to ligatures or undertake further intervention (Fig. 6)

The question now arises as to how many artenes should and may be ligated depends entirely upon the object in view If a diffuse gotter or more particularly a gotter caused by Graves disease is to be treated with ligation only the surgeon should not be too timid Ligatures applied to only two arteries whichever they may be do not seem to me sufficient to attain a lasting effect, even if the primary result appears satisfactory

For that reason I always heate preferably at one operation more rarely at two three to three and one half arteries i.e. all the thyroid arteries with the exception of one superior or the posterior branch of one. This opera tion if properly carried out, will by no means interfere with the function of the parathyroids According to the results of different surgeons their function does not appear to have suf fered even after the occlusion of all four thy rold arteries (Rogers) Still, for my part, I have until now preferred to confine my ligatures to three and one half arteries. We know for certain that ligation is only efficacious in cases of diffuse, and especially of extremely vascular goiters, and is even then not to be completely depended on. My later examinations of patients operated on have convinced me that only small diffuse goiters recede sufficiently Medium sized goiters certainly do shrink a good deal they cannot, however be reduced by ligation alone to any thing like the ordinary volume of a normal thyroid gland. The collateral circulation between the thyroid gland and its neighbor ing organs is, in spite of the absence of a more extensive arterial communication so plentiful that the gland remains viable even after the occlusion of all four artenes, if only it is not too radically separated from the sur rounding structures. Experiments on ani mals have also proved this fact.

In conclusion we have to consider the value of ligation in the various goiler operations We have employed it extensively in our surrical practice and are more and more convinced as to its advantages It is under stood that many operations especially enucleation can also be easily performed with out preliminary ligation. It has, in fact, been laid down as an axiom that enucleation should be undertaken without preliminary ligation so as to preserve as much healthy gland tissue as possible. This conception originated in an undervaluation of the advantages of preliminary hæmostasis, and especially in an undervaluation of the importance of the collateral circulation as a source of nourishment for the thyroid gland.

Now we know that the supply of blood to the remaining tissue of a thyroid lobe operated on is not endangered by the ligation of an in ferior if only the posterior branch of a superior is left intact, and if we do not un necessarily sever the isthmus with its border arteries Our subsequent examinations of cases operated on have indeed proved that the preservation of the isthmus (Fig o) provided this organ is not decidedly diseased in no way impairs the result of the opera tion. Therefore in the 250 cases reported in our statistics we did not once completely sever the isthmus. In only 20 cases, in which it was in an advanced goitrous condition, did we partially remove it. By the preliminary heation of an inferior - this is generally the more important artery --- enucleation becomes a much less sanguinary a clearer and a neater operation. At the same time we can avoid hasty clamping and too extensive pouch sutures when surprised by unexpected deep hamorrhage both of which steps mean grave risk for the recurrent nerve. If both lobes contain larger nodules the preliminary ligation of both the inferior arteries permit us to shell out neatly the largest nodules from both lobes. instead of restricting the operation to the more simple, but less logical excision of one whole lobe which always places the surgeon in a quandary if later he is called on to intervene further in consequence of the disturbance caused by the goltrous condition of the other

The foregoing remarks apply still more particularly to the operation of diffuse colloid gotters. The ideal method is then reduction of both lobes by means of resection which can be achieved without unnecessary loss of blood only by preliminarily ligating at teries on both ades. Then again it is better to ligate the inferiors, so as not to risk injuring the recurrent laryngeal nerve. If the inferiors and the anterior branches of the superiors are ligated on both sides the operation can in most cases, be performed calmly and without hemorrhage and an adequate supply of blood is insured for the remaining thyroid tissue and the partshyroid glandules.

THE RELATION OF ARTERIOSCLEROSIS AND OTHER ANATOMICAL CHANGES OF OLD AGE TO THE DEVELOPMENT OF CPITHELIAL MALICNANCY

A STUDY OF 206 CASES OF CARCINOMATA BY FRANK WARNER M.D. FACS COLUMBUS OID

N treating of the so-called precancerous conditions, various authors have pre sented us with an amazing amount of literature during the past decade result of these studies one practical result has followed The surgeon has been enabled to see and treat his cancer patients much earlier than before Less mutilation has followed these earlier operations and many lives have been saved that before would have been lost

Bloodgoods and others have presented the clinical picture of those breasts whose epithe lial cells are about to take on or recently have taken on an abnormal growth. He has given the surgeon a very tangible and useful description by which he may recognize those conditions of the lip which it not promptly and radically treated will destroy the nationts life

From a histological study of these precan cerous conditions a number of research workers, including Greenough and Hart well, Speese ' Klotz ' MacCarty ' Means and Forman have confirmed this work of Blood good and are agreed that the essential anatomical changes in these conditions are-

- I Increased activity on the part of the epithelium
- 2 Increase in the connective tissue espe cially in the amount of intercellular substances claborated
- 3 And lastly an obliteration of the lumen of the blood vessels

It is to be noted that a majority of the workers have been intent upon a search for landmarks by which the surgical pathologist might recognize the malignant change before

Bloodgood Serg Gyant & Obst 9 4, Evan, 9. Greenough and Hart ell. J Med Rescurch, xv 416. Speece. Ann Surg Phila 9 o, Feb klot Canadus M Ass J o M 9 M MacCarty Surg Gynec & Obst. J. IVI. 4 Means and Foreign Ohio 5 M 7 4. June. Iden Destal Sammary 9 5, Dec.

actual penetrition and infiltrition had taken place Same of them however have at tempted to submit theorie to explain how these anatomic changes might so disturb nu trition as to become factors in the production of currinoma

In a study of the only cancers which have been produced contentally and Wilbach are agreed that such cancers are the result of altered nutrition and this in turn is dependent upon a narrowing or oblite ation of the lumen of the subspithelial blood ve sels supplying a certain group of The condition tollows \ ray burns

Thalbabe ha pla ed great stres upon certum ild ag conditions as causative factors in the production of carcinoma

Chief among these old age conditions hav ing an etiological role he places endartentis When organs which have been He savs invaded by cancer are examined one u ually finds in the connective tissue about the growth very few cells blood vessels which are stenosed and with thickened walls and signs of endartentis obliterans. An exception to this is noted however in that the tissues im mediately surrounding the cancer show a more or less marked reactive hyperemia with cell infiltration u ually of slight degree

I drew the conclusion he con from these and many similar obtinues servations that the local disposition of aging tissue to cancer results from a diminution of the cellular elements and a contraction of the blood vessels in the connective tissue

In discussing these anatomic changes which are assigned by some of these workers an etiological role in the production of car Some accuse the obcinoma Loeb11 said

literation of the blood-vessels this condition it was argued forced the epithelial cells to obtain their food supply from the connective tissue cells which latter process was said to act in a similar manner as the penetration of a spermatoroon into an ovum a somewhat fantastic comparison with barely any foundation of fact.

Others assumed, he continues, that chronic connective-tissue changes liberated the latent energy of the epidermis. It is, however difficult to see why very dense connective tissue should as such be favorable to epithelial growth. In all probability he concludes, it would prove very resistant to the expansion of the epithelium. He dismisses the cutological importance of this infrosts with the observation that in many cases of cancer of the skin no such changes are found.

With this variation of opinion in mind it would seem desirable to take as large a number of carcinomata as time would permit and study them to ascertain whether these anatomic changes were at all a constant accompaniment of cancer. This is such a study based upon the examination of 200 cases of carcinoma. Their distribution can be seen in the appended table (see Table I)

Since most of the workers mentioned above have concerned themselves with arcinoma of the skin the epidermoid type will be con sidered first. The histological study of the condition of the timues involved in the epidermoid carcinomata revealed in many instances a distinct stenosis of the lumen of the arteries supplying the part, and frequently a like condition in the smaller vessels. In this study consideration has been given only to those cases in which the arterial changes have produced a stenous of such pronounced type as would indicate that it probably antedated the development of the cancer and of such a degree as to be capable of interfering materially with the nutrition of the area involved

The percentage of cases in which these anatomic changes were present varies with different sites studied. Whether these fig ures would hold if a larger series were examined is somewhat doubtful Seventy six epidermood carcinomata curring in various parts of the body examined 0f these 76 cases, 44 or 5 per cent, showed a distinct obliterative chin the lumen of the arteries. The connectissue surrounding 47 cancers, 65 57 per cof this senes was characterized by the presof few nuclei and a mitter large amoun intercellular substance. There was a malymphocytic infiltration present in 57 o per cent, of the specimens.

While this series is not a large one y does show one thing namely that t anatomic changes (obliteration of bl vessels and fibrosis) are not constant epidermoid carcinomata. It would there not appear safe to place too great st upon their ettologic role in the production this type of carcinoma.

Since afternal changes are known to one of the control o

since arreinal changes are known to so frequently in the uterus, it seemed to examine a series of non-cancerous error patients of the cancerous age as a trol. Twenty specimens from women of the control of the control

Of the 30 cases examined, 5 or 40 cent, presented endarteritis leaving 12 or per cent, normal vessels. Nine or 45 per chad an acciliular stroma. 3 of these with connective tassue increase and 6 with fibre Four or 20 per cent were infiltrated viprophocytes.

If this control sense is compared with cancers of the cervix it will be found 79 per cent had sclerosed vessels in the cers and 40 per cent in the non-cancer cervices in accillular stroma in 50 per co of cancers, and 45 in the non-cancerous ca a lymphocytic infiltration of 79 per centhe cancers and 20 per cent in the bercervices.

HAIR MATRIX CARCINOMATA

Thirteen hair matrix cardinomata is studied. Eleven of these cases were from face on or above the upper lip which quite characteristic of this form of can be consionally they do arise in other parts the body as in these cases one was from region over the scapula, and another from leg

The more amazeus

This type of cancer arises a, the name implies from the epithelial ells i the hair follicle. In their growth, tumo cell, of thi type tend to differentiate as do the cells c the hair matrix and form the characteri ti nbrils. Mallon

They also tend to form tubules as would be espected from their crigin. The cellthemselves are frequently pindled celled or uboidal, and often appear in a rather compact arrangement.

Har matrix carennomata seldom invade the deepe, structures and so are perhaps less malignant than any other type of carennoma Ir removed by a rather wide inci.ion they are not likely to recur. This is hown by two of my own cases in this series one or which was removed some nie years ago and the other two years without sign, of recurrence in either in, tance

In the examination of this group of 13 hair matrix carcinomata to of the cases howed a dense connective the use beneath the epithelium and surrounding the hair follicles which was poor in nuclei and rich in intecellular substances. Arternal tenosis will noted in only 2 or 28 2 per cent instances.

AN EA THE RAEA

Fits assett a nome of a local version of the entitlement to degree amount to ne apuble into mema, with the blood arms pur were revealed.

sin e the entineaum i the best seem to posses the power it aimulating the growth of innective time even to a marked extent in the benien tumber the so when had tumber of eighthelial tumber of eight mathematic way, not supprising to find connective time in all of these cancers except the most eight and rapidly growing one. Out if the entire group of ordiners of the breakt there were but 4 those of a medullary type that did no show about changes.

In a central series o ____ pearmens of abnormal involution of the bre-st only o cases 3 per cent, presented arterial selerotic change, and 16 66 o per cent, with in ultration of lymphosytes

All of the control sense exhibited abross, at the is a part of the hittologic picture of an involuting breatt.

From the fact that cancer of the breast is so frequently associated with abnormally involuting breasts many clinicians and path ologists have come to regard this state of the gland as a precancerous condition requiring removal of the organ

The vascular changes in the cancers were 58 per cent compared with 25 per cent of selerosed arteries in the non-cancerous specimens, and there was infiltration of lymphocytes in only 16 66 67 per cent, cases in the controls.

In studying the specimens of abnormal involution of the breast with reference to the anatomic changes of endarteritis, fibrosis and epithelial proliferation, it was found that the adni were not only increased in number but frequently the fibrotic changes were so marked that their secondary contraction had occluded the ducts, resulting in a formation of cysts, which has given rise to the more common term of chredic cystic mastitis

Often the acid and ducts were filled with proliferating cells but by carefully examining the surrounding connective tissue, it was plain that there had been no infiltration with epithelium. Not alone that, but the acid although greatly increased in number were more uniform in size than when the breast had taken on a malignant type of growth.

ADENOCARCINOMA OF THE UTERUS

A series of 8 cases of adenocarcinoma of the body of the uterus were examined. Five cases, 6.25 per cent, presented arterial obstructive changes 2 #5 per cent, were seel lular 3 375 per cent, had been infiltrated with lymphocytes.

A study of nine cases of non malignant uteri of the cancerous age was made. The uteri had been removed for various reasons other than cancer Three 333 per cent, presented sclerotic vessels one 11 per cent, gave an acellular connective tissue, but there was no lymphocytic infiltration in any of the o cases.

As will be noticed from this series the percentage of vessels scienosed was less than in the preceding cancerous series of uterl, although there they were involved in a little more than half of the cases. The same observation is true with reference to the condition of the connective tussue in the region of the car cinoma.

THE PROSTATE GLAND

Twelve cases of cancer of the prostate were examined. Four 33 33 per cent, of these specimens had been attacked by arterfo-sclerosts and 3 25 per cent showed the connective tissue to have been increased in amount and exhibiting few nucles. Lym phocytic inhitration was present in 0 cases 75 per cent.

McGrath¹ has called attention to the anal ogy which exists between the microscopical pictures of the epithelial changes in the cancerous process of the breast and prostate. While this study does not assign much etiologic role to vascular stenosis, it leads to an agreement with McGrath as to the nature of the process in both of the organs mentioned. Whatever stimulus initiates the process, it passes through a gradation of epithelial hyper plasta which is often easily followed in a single case Frequently the various steps may be seen in the same slide. Acini are seen in which both the inner and outer layers of cells are distinct (the primary hyperplasia of MacCarty) Other areas of acing exhibit a filling up with epithelial cells by a prolifera tion (secondary hyperplasia) and finally areas are found in which the epithelium has broken through and is infiltrating the surrounding tissue (tertiary hyperplasia)

CONTROL SERIES OF HYPERTROPHIED PROSTATES

Ten cases of hypertrophied prostates were cramined. The average age of these patients was 60 7 years. Seven of the prostates were cystic in type. But one of the cases abowed obstructive selerotic changes in the vessels. Hyaline degeneration was manifest in a number of the arteries of the specimen. Two of the prostates, 20 per cent showed acellular connective tissue increased in amount. Six, 60 per cent, presented lymphocytic infiltration.

By a comparison of the hypertrophied with the carcinomatous prostates studied, one finds to per cent of the former with scienosed

McCreth J Am. M. Am ben, see

vessels, while the latter shows 33 per cent with arterial obstructive changes

In the hypertrophies 20 per cent showed connective tissue increase of an acellular type while 25 per cent of the cancers of the same organ showed a like abrotic change Lymphocytic infiltration was present in 60 per cent of the hypertrophies and 75 per cent of the cancerous prostates

If obstructive endartentis is one of the occasionally contributing factors in the development of cancer at was absent in 8 cases. 66 66 per cent which had normal vessels out of the 12 specimens examined same holds true of the cancerous prostates in which fibrotic changes were present for 75 per cent of them presented a normal connective tissue

CARCINOMA OF THE OVARY

A senes of 10 carcinomata of the ovary were examined Three or 30 per cent showed vascular changes of an obstructive character But 1 10 per cent presented acellular fibrotic changes in the connective tissue Lymphocytic infiltration was present in 3 of the cases 30 per cent.

A peculiar feature of this series was the large percentage 70 per cent, of cases with normal blood vessels. Another notable fact was the absence of fibrotic changes in the ovary except in a single case of the series These facts stand out with increased force when we come to reflect that it is a very com mon thing to find ovaries removed for other causes in the so-called cancerous age per mented with sclerosed vessels also to find frequently fibrotic changes in these organs But here are 7 out of 10 cases with normal vessels in the presence of cancer and only I with fibrotic change while there are num berless cases of ovaries with sclerosed vessels and fibrotic changes without carcinoma. The type of the tumor might influence the findings somewhat, as 7 of these were papil lary cystadenomata

CARCINOMA OF THE STOMACH

Seventeen cases of carcinoma of the stom ach were examined Six or 35 52 per cent presented sclerotic arteries a very low per centage compared with what obtained in carcinoma of the cervix uteri Four 23 52 per cent showed lymphocytic infiltration which is small compared with some other Four gave an acellular connective localities tissue increased in amount 23 52 per cent

A very interesting question in regard to these cancers is whether they develop from preceding ulcers of the stomach or the ulcer develops from the carcinoma. By analogy we should expect to see a carcinoma develop from the fibrous tissue about an ulcer just as a cancer frequently develops from the fibrous tissue of an involuting breast and from the dense tissue following X ray burns We are all familiar with Mayo's views that cancer frequently develops from an ulcer Upon the other hand Stromever thinks the majority of these ulcers associated with carcinoma have been entirely secondary to the cancer, and have been superimposed upon it (Figs a and to)

The small series of twelve cases of adenocarcinoma of the intestinal tract, other than the stomach were examined Fight 67 per cent showed arterial obstructive changes 5 4 57 per cent a fibrotic change and 3 25 57 per cent lymphocytic infiltration of the specimens was from the œsophagus two from the ileum, and three from the colon Of the 6 cases of the rectum included in the above series there were 50 per cent with arterial changes one fibrotic and 2 with lymphocytic infiltration. In 5 of the cases of this series, the cancer-cells had shown their ability to stimulate the connective tissue overgrowth to an extent that had resulted in an almost complete obstruction of the ali mentary tract when this excessive tissue un derwent contraction for whenever newly formed connective tissue in a circular tube undergoes contraction as it will stricture results. But this is a feature that is outside the discussion of this study of the etiology of cancer

PRIMARY CARCINOMA OF THE LIVER

Four cases of primary carcinoma of the liver were examined But one of these cases showed arterial alteration of its coats, and no fibrotic changes were present in any of them

The rarity of the occurrence of primary cardinoma of the liver renders these cases of especial interest. This is the more true. since there has been so much written con cerning the relation of cirrhosis to primary cancer of the liver Many authors have em phasized the presence of cirrhosis in this type of cancer in a large percentage of the cases reported.

Winternitz, after quoting a number of writers who had presented tables showing the large number of carcinomata which had been associated with circhosis savs This table is of interest, since it points out first what a large number of cases of cancer of the liver are associated with circhosis and sec the tumor may occur in normal and diseased livers. In a tremendous per centage of cases the liver presents an ordinary type of curhosis. It is generally noreed that the cirrhosis precedes the neoplastic formation where these two are assometed. The tumor however brings about pressure atrophy directly and necrosis of the hepatic parenchyma through its excessive vascular involvement, and in this way a fibrosis may result secondary to the tumor growth. This is important since in a few cases those areas of liver uninvolved by tumor growth are likewise free of carrhosas Whether a cirrhosus may develop secondary to the tumor growth is uncertain but there is no doubt that the cirrhotic process is exagger ated as a result of this. That circhous is more frequently associated with cancers arising from the liver-cells than with those arising from the duct epithelium.

In the series of a cases studied by me the cancer arose in 2 cases from the epithelium of the bile-ducts, and in 2 cases from the liver cell epithelium. There was no cirrhosis in any of the cases. In one of the patients, o years old he was too young of course to have developed cirrhosus from the usual CAUSES

So whatever may be the cause of primary carcinoma of the liver neither vascular changes nor fibrosis could be charged as a causative factor in these 4 cases.

PRIMARY CARCINOMA OF THE LUNGS

The very respectable series of 4 cases of primary carcinoma of the lungs were examined. Owing to the rarity of the trouble, or seem ing rarity I felt I was fortunate in finding 4 cases put at my disposal for study in the Laboratory of Pathology of the Ohio State University A report of these cases has already been prepared for publication.

None of these cases had any vascular changes nor lymphocytic intiltration one of them was associated with fibrosis This one was an epidermoid carcinoma, apparently taking its origin from the bronchial mucous membrane

In interesting question at once arose as to how squamous epithelium forming the cancer could come from the calinted cylindrical epithelium of the mucous membrane lining the bronchial tubes. The answer comes from the belief in the metaplasia of one type of cell of a tissue into another type of the same tissue.

Virchow in 1854, propounded the theory of the metaplasia of cells of any type into cells of other types. Metaplasia occurs only within crtain limits Epithelial tissue can be converted into other forms of epithelial tlasue one form of mesoblast into another form of mesoblastic tissue

Adler in his monograph says transformation of one sort of epithelium into another usually of cylindrical or cuboid epithelium into squamous epithelium as has been found in many kinds of inflamma tory processes is well known

The theory of persisting and abnormally dispersed serminal centers and remnants while it cannot be disproved, is not necessary for the explanation of the so-called meta plastic transformations.

Haythorn observes

During the study of a case of unresolved pneumonia, one field was found which contained two medium-sized bronchi, the mucosa of which was replaced by granulation tissue covered by stratified squamous epithelium. Then as many as twelve bronch; were found which showed a like condition He concludes "Our finding in a meature agree with Schridde idea in so far as they how that the metapla the cells are newly formed cell and that they come from the growing layer. They seem to contradict the neces its of the presence of embryonic rest, as they could hardly have been so numerous at imultaneously to set up the proces in several different bronch.

Of the 4 cases of primary carcinoma of the lungs examined by me were upon the fight ide and 2 upon the left.

One of these cases No. os an epider moid carcinoma of the lung wa in a man o year old who had been a very heavy moker of the trongest tobacco. He had worked in a melting work where he inhaled very trong tumes of irritating gases. The chinical hi tors of his case na one of tuberculosis with out however ever having tound tubercle bacilli which had been sought for some niteen different times. The point of interest in this case so far as it concern, this tudy are the history of irritation over a long time presence of a distinctly abrou condition of the lung attacked and the metaply, ia of the tumor cell into a «quamous type

From the fact that this case was diagnosed as I under tand as tuberculos; of the lung clinically a is done in most cases of cancer of this organ, it may prove on more careful pathological study after death that primary cancer of the lungs is not so are a disease a is now thought to be. We know already that some cases of cancer of the lungs are militaken for sarconn of that organ.

not alone that, but also that there is a predisposition to cancer which is partly over come by this increased blood formation and activity produced by bleeding Bier's hy personic treatment and the injection of certain glands as the thymus the soleen and the uterus which he claims results in producing a leucocytosis that is detrimental to epithelial penetration. This is in keeping with the experiments of Loeb on the develorment of cancer in mice under varying in fluences of internal secretions. He says appears probable that with the co-operation of hereditary conditions all those internal se cretions are factors in the origin of cancer which initiate or sustain continuou periodic growth processes. In other cases mechanical stimulation of growth may take the place of chemical stimulation and again in others a combination of both may be These two sets of factors are present sufficiently strong to determine to a great extent the frequency of cancer in mice

Bearing upon the importance of lymphocytes as a protective influence against the development of sarcoma in rats which coincides with similar conclusions reached upon lymphocytes in cancer by Fischera quoted above Murphy has conducted some interesting experiments on the heteroplastic tissue grafting on rats from a mouse sarcoma. He found that in 10 rats which had been subjected to the influence of \text{\text{Tays}} for a

Les Losb, Starmes, zin, N e15, z₄ James R, Murphy M D Rackefeller Institute Report its 5,139. certain time sufficient to destroy the lymphatic leucocytes the tumor grew. On the contrary when the grafting of the same sarcoma was undertaken in 10 normal rats no permanent growth tool place.

Dr James B Murphs and John J Norton for the Rockefeller Institute made some very interesting experiments on spontaneou mouse tumors. He removed these tumors from 32 mice. He then placed these tumors from 30 parated on to a regulated losage of N ray treatment that was known to timulate growth fithelymphocytes. Then the tumors error replaced in the animals in another position. The result was that so per cent of the tumor grew lowly and 50 per cent failed. There were 3 per cent of recurrence in the old site of the tumor.

The next experiment was on two control series of mice likewise affected

First control. Twenty nine tumors were removed from as many mice and returned into the same animals only in another region without any treatment of the animal or the tumor 96 per cent recurred in the old site.

Second control. Ten spontaneous tumors were removed from mice and the tumors subjected to a similar dosage of X-rays as the original experiment. The tumors we then returned into the groun of the animals. The result was 100 per cent of growths and 40 per cent recurrences in the old site.

SUMMARY

- I have not found the various old age conditions of endartentis accillular connective tissue or fibrosis to have been present in all cases of cancer examined
- 2 In the study of the various abnormal conditions present in my control series of non-malignant uten sclerosed vessels were found without carcinoma.
- 3 Many uters with normal vessels showed the presence of cancer-cell infiltration
- 4 Many cancerous uter had only nor mal connective tissue consequently without tibrosis.
- 5 Inasmuch as so many of the non cancerous uten showed the so-called old age conditions one would expect to find cancer in them more frequently if they are a positive factor in the development of cancer
- 6 The same may be said of the overywhere it is quite common to find schrotic changes in the vessels and fibrosis in the stroma in the cancer without the patient having developed cancer.
- 7 Certain precancerous conditions do not necessarily develop into cancer. This is notably true in smokers burns some of which heal though simulating cancer. The epithelium in these cases sumply piles up with out infiltrating the tissue beneath.
- 8 Lymphocytic infiltration oven when present varied greatly in amount. This was true not alone of the cancers but also of the various tissues used as controls in some cases being very pronounced in others quite light

in amount. It was especially marked in the rapidly growing carcinomata.

CONCLUSIONS

- 1 (i) the 206 cases of carcinoma of all organs and region examined 105 showed arternal obstructive changes. This gives a substantially an equal division between endartentis 50 96 per cent and normal vessel.
- 2 Fibrotic changes were present in 118
- 3 Lymphocytic infiltration was present in 85 cases 57 per cent
- 4 That endarteritis and the anatomical changes of old age cannot be looked upon as a constant factor in the production of cancer is shown by the fact that normal vessels were present in almost half the cases
- 5 The same holds true of fibrosis or even acellular connective tissue without fibrosis
- 6 Lymphocytic infiltration while present in less than half of the cases plays a role that is protective rather than etiological
- 7 That certain biochemical factors of a local or internal and general type are probably responsible for some cases of cancer
- This study was made in the Pathological Laboratory of the Medic il Department of the Ohio State University through the courtess of Dr. Ernest Scott. Professor of Pathology Dr. Jonethan Forman Instructor of Pathology was my constant associate in currying on this study. Mr. Carl Hugger. As istant in the Department made the photomicro gruph. To all of these I am deeply grateful.

RUPTURE OF THE GALL-BLADDER ITS CAUSE PREVENTION AND TREATMENT BY W. GRANT M.D. DENYR CLEO. DO.

FLL authenticated cases of rupture of the gall bladder from pathological conditions are few and deserve always the consideration

of surgeons and internists.

Traumatism to the abdominal wall may well excite rupture of a distended diseased gall-bladder just as a similar blow to the lower quadrant might well aggravate a diseased condition of the appendix or a cystic growth, promoting or causing perforation

The usual condition predisposing to and causing perforation is an infection of the bladder usually of long standing. The acute phlegmonous condition is in itself not pri mary but secondary to a mild, but steadily progressive pathological conditions from in cro-organisms, usually the colon and typhold badill and streptococci, finally resulting in gangrene.

The progress and course is sumlar to that of the appendux, but not so rapid Gall atones will generally be found in these aggravated cases which result in gangrene and

empyems.
These conditions are the result of ignorance, neglect, and delay. The internist may not have appreciated the importance and significance of a clinical history consequently the surgeon has not had an early opportunity to reheve the condition by operation.

Prevention of infection must depend primarily upon healthy dietetic and living conditions and adequate elimination of intestinal toxina. Typhoid fever predisposes to gallbladder as it does to appendical infection.

Prevention of perforation or rupture must depend upon early operation. If this had been the rule in the past fifteen or twenty years, we would hear less now of cholecystec tomy which is fast becoming a fad.

Every novitlate and many who are not, seems to feel that he is not up-to-date unless in the swim of the latest surgical innovations. These innovations, in the realm

of the unknown but safely experimental fields, appeal strongly not alone to the progressive surgeon but more to that class of surgeons and physicians who pay in cash for business and are not much concerned about the nathological conditions.

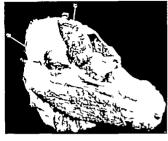

Past experience should inculcate lessons of value and of wisdom as in the popular and much abused operation of gastro-enterostomy for real and doubtful ulcers of the stomach and duodenum, and quite regardless of the important question of pylone stenosis — the one condition demanding operation that ad must of no debate.

I may be pardoned for introducing reports of two cases which are worthy of comment, if not also of record.

Cast J C M aged 5 fammer by occups ton, was operated on in 0.03 for gall-stoose—several being removed. The gall bladder was derinced and the wound or fatudous tract discharged bile for nearly—year before completely healing. The patient remained quite well until the spring of 0.4 when stomach dyspepsia recurred. This gradually increased until the night of Crober 0.04, when acute symptoms of perforation trended with severe pai chill, and fever were muddenly manifested. I have the patient next morning and operated immediately if was duckoed that in the former operation, the fundus of the bladder was stucked to the abdominal peritoneum, which was a common procedure at that time, but now justly bandored.

There was a rupture in the fundous and extravrastion of small quantity of pus but limited by omental softwores. There was no general peritorities. A smooth round stone as large as a large pecannut was removed and probably as a small stone was verfooted in the previous operation. It was lodged in dilated cystic duct and without difficulty removed through the bladder.

The bladder except a small part at the seat of perforation was not magnerous. This was rescribed with a small piece of openitum and the bladder with a mail piece of openitum and the bladder with the mail and the patient has been perfectly in the most hand to be patient by the stace. If had no plander. The manifals of the properties of the stone removed in the second openit.

Fg (all bladd showing to in the fund point of rupture

It might be asked why the gall bladder wa. not removed in such a case. I would an wer that in the absence of thickened rigid gangrenous wall there is no neces ity for its removal but some good reasons why it should not be Even killful urgeon over look the presence of mall stones in the bile What happens in such cases when the bladder is removed. The tone i too large to pass the ampulla or papilla. A second operation sooner or later becomes a necessity Every surgeon recognizes the increased difficulties it not danger also of secondary operation on the ducts due to adhesions and the destruction of natural guides and landmarks It is turthermore easier and safer to drain the gall bladder than it is the ducts. There is another objection to cholecy tectomy Inter titual pancreatitis is believed to be due to injection from the bile passages and the most effective treatment of uch cases i drainage through the gall bladder. If the gall bladder is removed the matter is need lessly complicated and the treatment more doubtful and difficult

I not the presence of the gall bladder as a receptacle and temporary reservoir for the bile worthy of consideration as serving some useful purpose

It the infection is easily remediable by a les radical procedure then it seems to me that cholecysto tomy should be the operation of choice. It should be remembered

that cholecy tect my 1 k n t rem ve the con titutional diathesi and intestinal toxic mia, which cyl t in intecti ns and gall tone disease.

CASE Mr M widow ag d 2 Li ing in mtortable circum tan e. Ha had oc asi nal attacks of call at ne obc for se eral year, which had increased in frequency and severity during the year 1015 On the fourth day of last January he onsulted me as to her ondition. I urgently adused immediate operation as the character and a ruteness of the attacks of cole with local manifes tations of disease indicated impending danger from perforation and sepsis. She positively and abruptly declined consideration of an operation. On Ian uary it she sent for me at night he had been suffering severely all day and evening from a villent and persistent attack of cohe she was vomiting The abdomen was generally distended frequently and the walls rigid. Notwithstanding my decided opinion that she was uffering from general septic pentonitis due to perforation of the gall bladler he r fused to go to the hospital or to submit to operation. In three days she died from scott peritoritis and paralyti ileus

I made a post mortem which re caled some omen tal addition and a pint of extravasated ble in the right kidney fossa. There wa no pu in it and none in the mail gall bladder which was contracted around a single round stone the size of a large olive. I remo ed with the gall bladder a porti n of the atrached liver tis ue.

Examination showed a small gangrenous area half an inch long and one fourth inch wid with a perioration of the diameter of a slate pendl (indicated by arrow in the photographi picture Fig. 1). On the reverse ide of the specimen (Fig.) in the substance of the li er. ill be seen a light colored and firm tone the axe of a small pecan nut. This might not he caused trouble and would not have been ilsoo ered or suspected in an operation. It was probabled in a branch of the head dut.

This patient's life was a needless ascrifice in refusing operation before the last attack and declining the only chance in the beginning of the fatal illness.

There could be no doubt as to the diagnosis and the necessity for operation. The very limited gangerne of the gall-bladder was doubtless due to the pressure and irritation of the stone finally resulting in ulceration and rupture.

Gall bladder infections are common and for

a long and indefinite period do not usually give rise to serious filness even in the presence of gall stones.

More consideration should be given to the early clinical history and to the conditions

which predispose to infection

The condition is curable only by operation and with early diagnosis and prompt choic cyntostomy gangrene will not be seen often The mortality will be exceedingly small without the use or necessity of cholecystectomy

PUERPERAL GANGRENE OF THE EXTREMITIES

By ARTHUR STEIN M.D. FACS NEW 1 24

Adjunct \ noting Oynersinglet, German Hospital Adjunct \ vectory Obstatrones, Harless Hospital

PUERPERAL GANGRENE OF THE EXTREMITIES NE of the most serious and intractable complications of the puerperlum and incidentally of pregnancy consists in puerperal gangrene affecting the lower and sometimes the upper extremities importance of this menace to childbearing women is plainly illustrated by the reports of 76 authentic cases in the literature including cases of gangrene after gynecological opera tions. The disease is however fortunately far from common The occurrence of two in structive cases in his personal experience led the author to make a careful study of pen pheral gangrene and the literature on the subject.

In view of the gravity and gloomy prognosis of the condition it seems advisable to bring the entire subject from pathogeness to therapy to the attention of the medical profession in general and of gynecologists and obstetridans in particular. The prompt recognition of incipient gangree is the only safeguard against a fatal issue or at best a marked mutilation of the extremitles.

The author's first patient a young woman them; years with gangrene of the right leg following abortion recovered after amputation below the knee. The second patient died of exhaustion with dry gangrene of both feet and lower legs after labor at term.

CAR: Abortion, curett ge gangrene of right leg moutation recovery

R. R. 20 years of age as dmitted t the Harlem Hospital New York ton June 0, 10 5. The patient was m the best of health and appeared t to an exceedingly normal and strapping young oman. The heart and I may were normal, the construit history normal, the urine normal. Temperature on admission was on and pulse on I find or as tion. Some alght bleeding I om

I ginal or m tion Some slight bleeding for vagina cervix admit one finger uterus about three months pregna t dnexa nd parametria perfectly ormal. D guessis Threatened abortion (infection)

Shortly after distalon she aborted three months fortus. There was foul of from the fortus as well as from the vagina. The temperat re on the next day dropped t normal only t rise again on the

same evening t ou and 5. The patient contin ed having a temperat re bet een ou and 5° for the next six days with no pains, however nd no other symptoms. On the seventh day after an examination by me it as decided t curett the patient as the terms was till enlarged and soft There ere umerous graylah white superficial Icers around the cervix. These ulcers were covered ∗ th umber of whitish membranes. After the curettage by which some placental than as removed the whole interior of the terms as well as the cervix was bbed with tincture of iodine This was repeated fo the ext seven days. Even after the curettage the t mperat re did of drop entirely but kept bet een o and 3 e 7 days after the curett ge the patient begs to complain f pains in he right leg and three days

lat that is on June 26 in 11 ten days fter the

curettage the right leg and foot began t swell

became cold, and howed violent bl ish incolora

The case is of interest because so far a. I uld find in Looking over the literature it 1 only the fourth case on record of gangrene following abortion Andérodia has publi hed ne case of a right leg becoming gangrenou after an abortion in the sixth month and nding fatally. The second case published by Bégouin and Andérodia occurred in a v ung woman in whom both leg became gangrenous and the right leg had to be amputated Here also death occurred In the case reported by them all andings showed that there was a vegetative endocardition

Fig. H Lilienthal' case. Post-operati gazgrene of fingers.

present. In Oke 5 (Simpson s) case the left hand was affected.

Case 2. Labo at full term, forceps delivery, aboughing of peripsel sutures, dry guspress of both feet and lower leps no operation death no topy. L. F. o years old, I-years was dimitted t the Barlem Hospital, New York, on June 105, full term of ber pregnancy in generally good condition. Her family and medical history irrelevant. Heart bornal lung, normal other internal organs, normal urtic at time of admission, normal no ordenia present. Westermann negatives.

On day of admission the patient was delivered with medium forceps. A second degree laceration was repaired with chronic catgot sources. The days after confinement the patient had a temperature of capts and slight chill. On examination t was rotteed that there were some slight laters around the cervit for which the patient received the ordinary treatment lodine applications and douches. The urine ow aboved traces of albumin and som bysulice casts. The temperature dropped t

and On the sixth day after confinement the sutures were removed because the whole area was sloughing

Ten days after confinement the patient still had irregular temperat res running up to 3 and rot, and even on the eleventh day a temperature up to og. She looked lik a very sick person although nothing could be detected outside of the local affect to rinfection the heart particularly seeming to be j good condition. Twelve days after confinement on Jone 7 the patient left the hospital against ou dwice only to return on July 3 that is seven days later in an eye and critical condition.

On her readmission (July 3) the beart-sounds were of good quality heart not enlarged, but its action rapid rat the temperature varied between o and of The abdomen wa held rind distinct masses could be felt.

In examination revealed that both feet aymmet rically for a dast to of about four inches above the nkles, a re discol red, nearly black, and the skin shrivelled Both feet were extremely tender on touch cold and in some places showed vericles filled with a whitish fluid. A diagnosis of typical symmetrical dry gangrene of both feet could easily be made. At bout four inches above the ankles on both sides the line of demarcation was well pro ounced on July 7 but the patient's general condition did not permit of any operative interference. There was no pulsation of the femoral artenes She finally died July 10 due to extreme Several blood-cultures exhaustion and dehility showed that there was no general sepsis. It was impossible in this case for us t get an a topsy so we can only suess at the real cause of this symmet rical sungrene.

In both of these cases we have had to deal with a nuerperal infection, in the first case of a rather slight nature and in the second much more severe. In the latter case I would like to advance the following explanation of the occurrence of the symmetrical A thrombus left the uterus and gangrene migrated into the uterine artery and from there into the internal flux and common flux artery up to the bifurcation of the aorta where it also occluded the other common iliac artery and by doing so caused the symmetrical gangrene on both sides. This was not the case in our first patient. As can be seen from the description, the onset of the gangrene was rather slow and the gangrene itself of the moist type. This immediately suggests an occlusion of the venous system in the affected limb with the arterial supply still working I am inclined to believe that the complete venous obstruction was the primary incident

and that the peroneal artery became ob structed only secondarily. It would be wrong to assume that the obstruction of such a small vessel as the peroneal artery could be the only cause of the gangrene of the entire foot and lower leg. I therefore think that for reasons stated above we have to deal in this particular case with an instance of arteriovenous occlusion of the affected area the venous obstruction being the primary affertion.

The following discussion deals with gin grene due to the puerperal state and affecting Diabetic gangrene and the extremities gangrene due to poisons (secale cornutum for instance) are not included irrespective of the puerperium cases of the latter kind were not uncommon in Italy some years ago Obstruc tion of non puerperal vessels for example in the brain causing puerperal aphasia as in Sinclair s1 patient is outside of the scope of the present consideration but it is note worthy that the years in the lower part of the right leg became thrombotic. Inother observation which requires separate mention 15 that of Schulz 2 who referred the peripheral gangrene of his puerperal patient to post typhoid anæmia and resulting nutritional disturbances in the central nervous system There was no evidence of thrombosis Seidelmann^a reports a case of symmetrical gangrene of the upper extremities after pneumonia in a woman 29 years of age who about three weeks previously had been delivered of twins. As may be seen from the case histories appended to this article peripheral gangrene has frequently followed childbirth after even longer intervals in consequence of septic endocarditis and embolism so that there would seem to be sufficient reason for accepting a puerperal origin

Raymoud's disease (as is perhaps not gener ally known) was observed for the first time in a young woman four months after childbirth and since that time (1862) has been reported as occasionally coincident with the pucipe rium. The disease as described by Raymoud is characterized by the absence of a material

Luncet, Lond on July 25 sea

appreciable obstacle to the course of the blood whether arterial or venous According to the description of v. Mehring' a prolonged circumscribed vascular spasm leads first to symmetric discoloration and finally to gan grene with shedding of the affected tissue areas sometimes entire phalances seems to be no reason to doubt that Raynaud s disease may appear as a manifestation of syphilis as well as of other infections special interest from the present viewpoint is the heading of Raynaud's case report as follow . Local asphytia of the feet hands nose dry gangrene of the four extremities going on to the fall of many portions of the ungual phalanges the whole supervening on a recent parturation. Recovery

The investigations of Buerger who studied the vascular lesions leading to presentle spon taneous gangrene refer to thrombo-angutis obliterans the endarteritis obliterans of German writers a specific disease which must not be confused with the conditions leading to puerperal gangrene of the extremi ties. There is no reason for assuming that the specific type of infectious organism which he considers responsible for thrombo-angulas obliterans is identical with the pathogenic agent of puerperal gangrene a condition in all probability due to a mixed infection only similarity consists in the development of certain purulent foci strongly suggesting the presence of some specific tomn or more probably some microbial agent. Buerger points out that spontaneous gangrene can occur in the presence of patent vessels and of periph eral nerves in which no significant changes can be detected. In all the examined cases of puerperal peripheral gangrene organic vascular disease was either demonstrable or the impending changes had been arrested by the rapidly fatal termination

Etiology Widely scattered among the many millions of births registered in civilized communities statements are recorded concerning complications on the part of the vascular system in form of puerperal gangrene

Mietl d med the d Hers, K ankenbrus as Be mucha ag Deptache Arch / khn med Sig, xxvv 26 Deptache Zischr (Vervenh 004, xxvs,

Lakrbock der moeren Mehnin 9 g u., 9 M. Raymed Lecal A-physia and Symmetrical Gangress of the Extremities Transf telly Di Barbor Sekendel Monographa, published by Sydenham Society 282 p 73 J.M. Research 5, 7 t.4, 8 Am J.M. Sc. 9 g.c.dix, o.

of the extremities. Different types of vascular obstruction in form of arterial venous or artenovenous blocking with or without changes of the heart valves, may all culminate in the clinical picture of gangrene. Puerperal thrombosis was found in 76 of 34 951 cases (o 22 per cent) by Klein1 25 cases being frankly due to infection alone. Fatal em bolism occurred in 4 cases (o.or per cent) In other words there was one thrombosis in five hundred births and one embolism in nine thousand births. Jaschke³ mentions one thrombosis in four hundred births and one embolism in nine thousand births. A very important cause of origin of thrombi is a considerable loss of blood whether due to parturition, operations or other reasons. An abnormal constitution of the blood favoring the onset of thrombons was described under the name of thrombophilia by Mendel.

Pempheral puerperal gangrene of venous organ is very exceptional although diseases of the veins of the genital apparatus in form of varicose and thrombotic veins are of common occurrence during pregnance as well as in women who have borne a large number of children. Phiegmasia alba dolens due to obstruction of the illiac veins with periphiehtus and retrograde lymph stasis is an occasional important complication of the puerpernum, but rarely if ever terminates in rangerene

The arterial origin of peripheral puerperal gangrene is by far the most common and is probably always due to infection. In animal experiments on guinea pigs and rabbits in which extensive thrombi were produced under strictly aseptic conditions, not even the slightest tendency to a rise in temperature could be noted by Nakano This strongly suggests the probability that the very common rise of temperature in thrombosis after childbirth is always referable to infectious causes. Thrombosis of the arteries of the leg might be due to an ascending thrombosis of the uterine artery from its terminal branches at the site of the placents, the thrombosis extends into the common iliac and even into

Arch L Oysnesk 19 mrv Zestrabl, f. d. Orsnesph, d. Missi. Cher. 12, 2004. 3 Moreches, med. Wchenche: 509, 281, 149 Zircher f. d. 500, septer Med. 1812. 35, 54 the aorta, or it may be continued downward into the external fliac, the femoral artery and its branches. The smaller blood vessels sometimes become obliterated through embolic plugs which have become detached from the thrombi in the large arteries. In favor able cases the onset of gangene is prevented by the establishment of a compensatory collateral circulation

collateral circulation

The cases in which tissue necrosis does not occur until both vascular systems have become blocked and impermeable constitute the group of arteriovenous puerperal gan grenes. In other cases the blood coagulates secondarily in one system due to complete interruption of the circulation in the other It is sometimes difficult if not actually impossible to decide if a given case is of mixed arteriovenous origin on account of the difficulty of ascertaining if the thrombi found in one system are of etiological importance or have formed secondarily without contributing to the production of the gangeme.

Although the reason still escapes us why in certain cases the spite or tone process becomes localized in the internal wall of an artery and in other cases in the venous wall or in both the most common cause of puer perul peripheral gangrene is known to be a spitic or tonce endarterities and embolism from diseased heart valves usually occurring in cases of grave puerperal pyemin.

Infection no matter how sheht and appar ently irrelevant is invariably present and undoubtedly is always responsible for the conditions leading to gangrene of any kind Childbirth and the puerperium naturally afford numerous opportunities for infection a very common and extremely dangerous avenue being represented by thrombi at the site of the placenta in the puerperal uterus. The ubiquitous streptococcus, often in association with anaerobic microbes has been demonstrated as the infectious agent in some of the examined cases. Not only the bacteria them selves, however but their toxins play an important part probably through lesions of the vascular endothelium which in combination with the altered condition of the blood during the puerperium predisposes to the formation of thrombi. In this connection

the contribution of Eichhorst, on gangrene of the arms and legs after scarlet fever and other infectious diseases is very instructive retarded coagulation of the blood in puerperal women was recently demonstrated by Kott mann 1 Mechanical factors the recumbent position and relative immobility of the entire body also enter into consideration as possibly lowering the resistance against infection through retardation of the vital processes. It is suggestive that the majority of these gangrenes concern the lower extremities although the upper extremities are occasion ally involved and in exceptional instances different extremities with other parts of the body may become gangrenous.

According to the fundamental teachings of thrombosis coagulation of the blood results even in the presence of a sufficient circulation whenever the endothelium of the blood vessels is damaged in its nutrition and thereby in its physiological function Besides septic infection other causes such as a weak ened heart action probably play only the part of the last determining factors Post operative thrombo-embolism was directly referred by Fraenkel' to septic infection having its entrance avenue at the operation wound and the same is undoubtedly also true for more distant puerperal thrombi which are likewise referable to a focus of infection Arterial thrombosis is either the result of a preliminary change of the vascular wall or of a change in the composition of the blood or of a combination of both these factors. Changes of the blood itself usually affect the small and medium sized arteries exclusively whereas very large vessels may be blocked in consequence of lesions of their walls through microbes or their toxins The pathogenic agents may lodge in the arterial intima giving rise to obliterative endar tentis or the germs in the circulating blood may be arrested in the endocardium where they cause an ulcerative endocarditis which in its turn leads to embolism and death of the hmb or the patient herself

The extremely variable cause of the ob struction in the arterial and venous system

Symptoms The phenomena of incipient

gangrene are identical with the of mechin ical obstruction of the block vessel and naturally vary according to the mode of origin and the path if the intection in a given Pain is very pronounced and never absent in extensive vascular obliteration such as lead to peripheral gingrene. Infretion usually being the ettal great factor the ordinary symptoms of purperal tever are apt to precede the ign of ti ue necrosi Septic puerperal endometriti is present in the majority of the cases. In milder cases only a rise in temperature will indicate some slight infection. The mode of onset of the gangrenous symptoms will sometimes though rarely suggest the cause and seat of the vascular obstruction A sudden onset usually points to embolism in the arterial system (dry gangrene) while on the other hand the gangrene may develop very insidiously in the case of a small embolus. The onset of gan grene may be abrupt or gradual also in cases of purely venous obstruction (moist gangrene) so that the rapidity of evolution of the symptoms permits only an uncertain conclusion as to the seat and origin of the obstacle general practical way it may be said that the early appearance of gangrene in the first few days of the puerperium points to an arternal (the most common) origin

The manifestations of puerperal peripheral gangene do not require a lengthy description. Ande from the severe pain already referred to the absence of arterial pulsation below the thrombus or embolus is an important age characteristic of the cases of arterial blocking. The sensibility is usually distinctly diminished, while the motility may be preserved. A livid discoloration and a relatively diminished temperature of the affected area add to the probability of incipient gangene. In cases of venous origin the inflamed veins of the pelvis are often distinctly pulpable by the rectum or the vagina due to the existing thrombosis and periphlebtic externs

The two forms of dry and most gangene are apt to be combined in the same case, depending upon the rapidity of complete inter ruption of the blood current and the presence of external factors which favor munimification. Although the intolerable pain subsides as a rule when the gangerne has become established, the patient's general condition now becomes seriously aggravated through the absorption of necrotic tissue constituents. Before demarcation has occurred deeth may supervene under increasing pulse and temperature especially in cases of arterial obstruction.

Prognosis The prognosis of puerperal nempheral gangrene is governed in the first place by the timely performance of amputa Unfortunately amoutation is not tion. always practicable on account of the bad general condition, the rapid progress of the cangrene or because the sent of the obstruction is located high up in the aorta. Puer peral peripheral gangrene has accordingly a very bad prognosis as one half to two-thirds of the patients die for we are not able at the present state of our knowledge to prevent such an unfavorable outcome While the mortality is still deplorably high it has nevertheless been lessened by one half since the institution of modern measures of treat ment. The arterial venous or arteriovenous pathogeneses probably have no marked bearing upon the prognosis or the mortality although it appears that the mixed arteriovenous type of puerperal gangrene is credited with the most favorable figure

Treatment The treatment of indipient puriperal peripheral gangrene consists of purely conservative measures applying simply to the prevention of thrombous and embolism by means of elevation of the extremtly heart stimulants judicious transfusion and similar measures. The appearance of the line of demarcation is the signal for surgical interference. Although the dangerous symptoms may apparently subside because the organism endeavors to resist the absorption of decomposition products from the necrotic area it is imperative to remove the gangrenous part as promptly as possible for the safeguarding of the patients life.

The prophwars is limited to the ordinary ascritic and anticeptic management of all deliveries, strengthening of the general circulatory conditions through elevation and gentle massage. When through leavation and gentle massage. When through have formed elevation of the part is the best treatment to prevent their progress. Premature movements favor the onset of embolism and en danger life.

The manifold instructive features of these cases are best brought out by a comparative study of the material in the general literature. The compilation of authentic cases from the hterature of the world brings the entire num ber of observations up to 76 including 6: cases of peripheral gangrene following labor with one personal observation (author second case) a cases after abortion with a personal observation (author's first case) four cases occurring in the late course of pregnancy and 5 cases after gynecological operations which have been added for reasons of completeness. Twelve years ago in 1904 a list of 80 cases was published by Wormser but this contains a number of observations which are not verifiable or do not properly belong under this heading. In order to correct another statement of Wormser's the author wishes to state that Begg's article was pubhahed in the Laucet in 1870 and not 1876 Inaccuracies along this line are especially common in the French literature where, for example a case is persistently credited to Roux instead of to Rouse, an English con tributor to the Lancet in 1806 Moreover

Lafond and other French writers cite 4 cases by Simpson and apart from these the obser vations of Cowan Bottomley (called Bossomby) and Reid which are precisely the cases reported by Simpson

The following cases all very old incompletely reported and partly inaccessible in the originals are cited after Wormser 1

CASE 1 Unnamed observer in 54 Rec period do ba. de med de chir de Pharm Par vol 1 p 149, described gangrene of one extremity twelve days after labor amputation on the same das with out noticeable arterial bleeding. The oth r lower extremity, was shortly afterward affected in the same way and the patient died five week aft r conhamement. No autopsy

CASE 2 Latham Med Comment on using described nease in a woman between 10 and 40 of three fingers of whose left hand gradually became quite putted one week after childbirth and were temoved without pain or hamorrhage. The condition recurred about six days later and at the end of another fortinght the part below the wirt were removed. Finally the ulna and radius became loose and were east off but the patient recovered.

CARE 3 Coctsem Ann Soc de méd le (and 1835 Puerperal gangrene of upper extremuties nosc upper lip cheeks also gangrene of the right leg and knee

CASL 4 Tonnelé Arch gen de med 1840 ANI 4 2 Case of puerperal gangrene in a primipara of 24 developing eight days after deliver; in different regions of the body including the anterior portions of the thighs and the heels Death on tenth day CASE 5 P E Edouard Raymand These de doet

CASE 5 P E Edouard Raynsud These de doct. Paris 1841 Puerperal gangrene of part f both arms cheeks and chin.

The majority of the cases 53 in number concern peripheral gangerine of the lower extremities. The left leg or foot alone was affected 16 times the right leg or foot alone 75 times both lower extremities 15 times. In 3 of the case reports the affected side is not specified. In one instance (Begg s case) both hands both feet, the tip of the nose and portions of the ears were gangerious. Maurice Raymaud's case fifteen is similar to this. In Rouse's first case both legs hive fingers and the right ear were affected. MacFar lane 8 patient had gangene of the right leg and right arm and Lever's patient of the left legs and left arm.

Following abortion gangrene of the lower extremities is represented by only three weeking Randicks 2004, willi 75

cases of which one came under the author's personal observation and was followed by recovery. The right leg as in the case was likewise concerned in a case with a tatal outcome reported by Anderodius. In mother case (Bégouin and Anderodius) both lower extremities were involved and the right leg was amputated but without saving the natient's life.

Gangrene of the upper extremities a relatively rare puerperal complication is noted in 10 cases live of which concerned both arms one with involvement of the legs one the left and one the right arm. In one in stance one tinger of each hand was affected in another the ingers of both hands finally in one case there was symmetrical gangrene of the ingers toes and ears. Following abortion there 1 only one recorded example of gangrene of an upper extremity namely. Ohe sease (Simpson) in which the left hand was affected.

The rarity of peripheral gangrene during pregnancy is illustrated by the scanty number of corresponding observations on 4 cases. Three of these cases concerned the right leg one (which ricovered) with simulatineous slight involvement of the left leg. In the fourth case the little finger of the right hand became gangrenous and was amputated All these cases occurred in the latter part of pregnancy.

Lempheral gangrene as a sequel of gyne cological operations has been reported in 5 cases which for reasons of completeness have also been tabulated. In the voungest patient a primipara of twenty years with severe puerperal infection requiring abdominal hysterectomy both legs were affected by sym metrical gangrene and amputation was per formed with a successful outcome. The other four patients elderly women died one with gangrene of the left leg one of the right arm and one with gangrene of one lower extremity which was amputated without saving the patient's life. The gynecological operations which had been performed were laparotomies for ovarian sarcoma multiple or unusually large myoma abdominal hyste rectomy and cophorectomy plus appended tomy (Lilienthal's case)

The above figures are given approximately rather than accurately for it will be readily understood that some of the cases belong to more than one group while in others no de talled statements are available.

Arterial obstruction through embolism or thrombosis due to endarteritic changes is especially noted as the cause of the gangrene in 20 cases. Disease of the heart (vegetative endocarditis nortic stenosis thickened mutral valves etc. etc.) alone or in combination with arterial obstruction are noted in 13 cases and persistent foramen ovale in 3 cases. Here it must be emphasized however that many cases did not come to autopsy and are incompletely reported in this respect the observer leaving the cause of the gangrene an open question. Obstruction of both arter ies and veins was present in 12 cases Berr s case being doubtful however Venous obliteration alone was apparently responsible in o cases (Willcox's case being doubtful) In Schaeffer's case no changes at all were found neither in arteries nor veins. In a out of 4 cases of post-operative gangrene it is stated that the arteries were thrombosed

Very rarely and as a suggestion rather than an assertion a patent foramen ovale is men tioned in explanation of a paradox embolism as in Oliver's first case and in Willcox's case However Popow directly charges the open foramen ovale with the responsibility for the nuerperal gangrene of both arms in his case. which was free from endocarditis. Among the seventy five tabulated cases, thirty three milents recovered and forty died. In two instances (Cowan a second case and Dickinson and Hubert's second case) the outcome is not stated. Only 4 among the 33 cases recovered without an operation (Gutbrod a second case Dickinson and Hubert's first case Seldelmann and Schulz s cases)

The presence of an infectious disease was noted in several of these cases. The perpheral gangrene in Schula's patient developed after premature labor at the end of the third week of typhoid fever. In Seldelmann's case the gangrene followed on pneumonia. Oliver's second patient had pneumonia of the right lung. Pleurisy is stated in one of Cowan's cases.

Puerperal fever and obliterative endarteritis preceded the gangreno in Etiennos case six months after childbirth. Severe puerperal infection necessitating aftdormal hysterec tomy is noted by Roux de Brignoles and Auriantis. Puerperal ulcerative endocar ditis as a forerunner of gangrene is men tonned by Bané and du Casel

General sepsis is mentioned three times and pynemia once in association with puer peral gaugeme of the extremities, and Montault's patient suffered from peritonities with probably general sepsis. In altogether six cases peripheral gangrene occurred in combination with eclampia. The occurrence of puerperal mania is specially mentioned in two observations.

From the forensic viewpoint, the sporadic occurrence of puerperal peripheral gangrene is very important in so far as it may strike when least expected in an apparently uncomplicated case like lightning from a clear sky Forewarned is forearmed and the large col lection of cases from the literature will serve as a helpful precedent. It is also in this regard that the author hopes to have offered a serviceable contribution to surgical gyne cology in supplementing his personal observa tions with the interesting material which is so widely scattered in the general literature Although the co-operation of unfavorable circumstances which lend to peripheral gan grene can hardly be foreseen and prevented. the safety of our puerperal patients will be decadedly enhanced if the possibility of such a formidable complication is kept in mind That youth, a healthful condition, and a normal labor do not afford protection, is shown plainly enough in the cases embodied in this paper. A thorough knowledge of the predisposing causes and watchful care at the bedside are the only means to check a further extension of the list of peripheral gangrenes due to the puerperal state.

about s inches below the knee were entirely ansesthetle and cool. As apparently the gangrene spread rapidly amputation also e the lines was performed. Five days after operation patient was decid-vily better but she died three weeks after operation \u2212 utops.

Examination of amputated leg sho ed embolism of populteal receive extending into its two branches all the

vens contained coagulated blood (thrombi)

This second case is remarkable because the endocarditis developed so to say under the physician's eyes (similar to Wormser's first case). The thrombosis of the veins is also of a secondary nature. It is clearly a case of general sepsis similar to Winckel's case.

In Oliver's first case it is also remarkable that the gangrene developed so quickly that in 4 days after the onset of the first pains amputation of the thigh had to be done. On the fourteenth day after confinement general debility and paresis set in due in Oliver's opinion to embolism of one of the arteries of the brain whereas the obliteration of the popliteal artery was consequent upon the action of a poison causing clotting of the blood

The heart was normal If that was the case there is only one explanation of this case similar to Wanner's case and that is that there was an open foramen ovale 1e an embolism from the side of placental in sertion The embolus is not thrown from the right auricle into the right ventricle and from there into the pulmonalis but finds its way through the open foramen ovale into the left heart and divides itself there into different parts. Small particles were thrown into the left caroud and gave rise to the em bolus in one of the arteries of the brain where as the bigger part of the embolus is thrown into the cruralis where it forms a total occlusion of that artery The clots in the veins are apparently of secondary nature as there is in the clinical picture no signs of any phlebitis.

It is hard to give a satisfactory explanation for the extremely quick progress of the gangrene

Overnises. A case of phlegmasia dolers, terminating in gangrene of the foot. Amputation, Recovery Med & Surg. Reporter 1875 xxxiii 117

The patient, a woman 34 years of age, developed gangrene of her left limb about three weeks after the birth of her eighth child. Severe pain in the limb which was swellen and tender especially along the course of the femoral venesis was felt first n the ninth day after confinement and fortalght later evidence of gaugene was zero on the liner side of the best rapidly promoting and larading the entire foot. Amputation is performed at the lower third the welling disappearing rapidly and the patient loss than two months later was discharged with good stamp, and beath to employer performed. At the time of the operation the large arteries were found completely obstructed.

Two weeks after adminison, there are it is very rapidly programming pargran. If the right foot of the park of the result of the right from of the virtual of the size of the refer and emisteration of the refer and emisteration of the larger strength.

It is a question whether this second case can still be classified as a case of puerperal gangrene since the symptoms set in three months after confinement, but the possibility of a connection cannot be denied. The case also is of interest because it was shown microscopically that both the arteries and the veins were diseased.

On the seventh lay the nation complained of pain in the left kg expectably in the affi realibility lessened on the inner side. (the thigh suphema scratifice. On the kilth day points in key reportably in foot increased slight cedema. Finally a dry gongreeo f the whole foot set in with line of demarcatio above the ankl. On the thirty ninth day post pa turn amputation of the leg. Recovery.

Anatomical examination. There are no thromb in the final post 1 the arteries of the foot are filled with thromb. All the sense re-clotted. On the day pather was transferred t the surgoal clinic a slight syn the murmur was found t the base which was not present before that time.

In this case the endocarditis without causing any symptoms was probably the cause of the emboli m. (The endocarditis is not

Werchell, F. Die Pathologie und Therupie des Wochen bettes. 3r ed. 9 8 p 3 2

essential to bring about an embolism as is proved in Winckel s case.)

Zametom E. Ueber Gangraen im Poerperium. Ergebn. d. Gynack., 9 4 p 25 (This case is identical with that reported by Guggisberg, Verhandl. d. deutsch. Gessellsch. f. Gynack. xv Kong. fl., 3.)

Patient 5 years old II-para. Four days after confinement alight manifels on left side. Five days later patient out of bed. Seven day later recurrence of mastitis. On following day pains in both legs especially in calves and toes. Heart normal. Bhrish spots on dorsal and plantar surface of right foot, and total analyseds up to about cm. above malicell. On the day following also bluish discoloration of left foot but its circulation was gradually re-established, with marked hypermethesis.

Demarcation of gangreese on right foot.

According to Zbinden patient was discharged without amputation being performed whereas according to Guggla-berg' above-mentioned communication the gangrenous part of the right foot was amputated. The uthor thinks that in this case the gangrene was due t ergotin because as he says the symptoms appeared simultaneously in both lers. I am rather inclined to believe that here too we have to deal with an infectious process (mastitis being present).

B. PUERPERAL GANGRENE OF THE UPPER EXTREMITIES

BILLBOTE. Chir Klin., Berl., 87 p. 429

Spontaneous gangrene of forearm of puerperal origin. Patient was woman 55 years of age near the end of her sixth pregnancy. Four days before an easy labor at sith programcy. Four days below an easy fallor at term, she left pain her left hand, and two days later at term, she left pain her left hand, and two days later at tenties upper extremity was swoken, up to the anila. Sowen days after the onset of the pain the fingers became blue then black, and the gazgress rapidly invaded the forearm. Amoptation of the Enth, t the middle of the forearm. Amoptation of the Enth, t the middle of the arm, on the twentieth day after the appearance of the pain.

Complete recovery within one month after operation. Biliroth did not see this case himself, but from the description believes it to have been due to embolism of the tinar artery probably referable to endocarditis, with vegetations on the sortic valves. H states that he observed an entirely analogous case also originating during pregnancy of spontaneous gangrene of the leg in Zürich

Report of case of bilateral embolic mastitis. Patient was admitted to hospital in state of pronounced septic infection and promptly succumbed to the disease. She had moreover an aboves in the right lobe of the thyrold gland, and gangrene of the third phalanx of the fourth finger of the right hand, and the idth finger of the left head

Powow Gangraea der oberen Extrumitaeten im Puerpe rium. I f Gebortsh, n. synnek... oon, No. 8 (Russian) rium. J f Geburtsh. u. gynaek., 900, No. 8 (Russlan). Zentrafbl. f Gymeck., 9 o, No. 47 1459.

Primipara age 36 years, came under observation on eleventh day of puerperium, after normal and easy labor left arm was discolored almost up t elbow covered with venicles, cold, without sensetion or motion right arm was similarly changed on anterior surface of the forearm and in region of the fourth, fifth, and in part of the third finger.
Rise of temperature had begun since fourth day of puerperium and patient noted first red, then purplish spots, with pain, in the arms, as outlined above. Lines of demarcation began to form on twentieth day after delivery and the left arm was amputated at the upper third of the humeron. set arm was amounted at the upper thrit of the france in Resection of gangrenous portions of right arm followed by transplantation of airin on the granulating surface. Patient made good recovery Old emboll were found in the left radial and ainst artery and a similar embolus was assumed in the right ulner artery. The arterial walls were entirely unchanged. The veins were entirely permeshie and empty. There had been no cardiac symptoms t any time, and there was no evidence of endocarditis. The emboli were therefore assumed to be derived from the uterine veins, bence they reached the general circulation through patent foramen ovale.

SCHULZ, R. Mittl. a. d. med. Abt., d. herrogi. Kranken-hames zu Braumschweig: Deutsch, Arch. f. klin, Med 884 XXXV 56.

Printpara, are g years, premature labor (7 months) t and of third west of typhold fever. Soon afterward, after severe collapse parenthesis and tingling sensations first in feet then in finger tips, with swelling of legs. In part

superficial, in part deep gangrene of circumscribed skin areas in exactly symmetrical localities of the legs, upper and lower arms and chest. The fingers and toes were not gangrenous. Moderate pala in the affected limbs No evidence of thrombosis, no thrombotic strands could be pulpated. Recovery The condition is referred by the observer to post-typhoid anamia and resulting nutritional disturbances in the central nervous system.

SEIDELMANN Deutsche Zischr f. Nervenh. 100.1 xxxii. 114.

Case of symmetrical gangrene of the upper extremities after pneumonia in a woman 20 years of age who about three weeks previously had been delivered of twins. Although the attack of pneumonia is credited by the observers with the responsibility for the onset of the gangrene he admits that puerperal etiology cannot be altogether excluded in view of the relatively recent childbirth.

ZECOPN EXIST Ueber Ganeraen im Puernerium. Ergebn. d. Gynaek. 9 4 252

The following case is identical with that briefly reported by v Gueunberg in Verhand), d. deutsch, Gesellsch, f. Gynack, rv Cong vol il 2 3

Patient ro years old, II-para. Three days after normal confinement chills and high temperature. On the ninth day very pronounced pains in the whole of right arm orderna of same. A few days later cessation of pulse in ulmaris and radialis, no sensibility First livid dis-col ration, finally bluish black color Small vesicles on epidermis. Marked odor Blood culture hemolytic diplococci Gram positive. On fourteenth day after con finement systolic murmur On seventeenth day after confinement amputation in the middle of the humerus for gangrene. Subsequently patient went through a very serious pyremia but finally left the bospital cured

Examination of amoutated arm. The brachial artery is patent about 5 cm. below its bifurcation. There is an embolus to be found in the radial as well as in the ulnar artery occluding these two vessels entirely Bacteriologi cal examination of these emboll shows diplococci, Gram positive.

Author thinks that in this case the embolism was due to an existing endocarditis.

ADDENDA

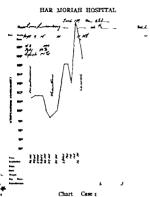

Through the great courtesy of Dr Howare. Lillenthial of this city I am able to add an interesting case of his to my paper and want to take this opportunity of expressing my appreciation to him. His case is the fifth of gangrene after gynecologued operations and the secony-maths in the whole strics.

H Lilienthal a case Post-operat re embolic gangrene of fingers amputati n of fingers

Mrs R & 8 years old, entered Mr Sinal Hospital on Detember 16 9 5 Tempersture 99 5 pulse on respiration 4. Thirteen years before as had had post bortive septis. Five years before she had been operated upon at Mr. Sinal Hospital for dynamenothers. Four months before her appear dix and right vary had been removed in a bouplus, in another city and ventral surpension had been don. At the same time an exploration of the upper belomen had been made. The patient stated that gastrotomy had been performed but as to this there is some doubt.

Afenstruation had begun when the potient was 4 years old and for 3 years bef re admission had been very painful.

About len days after the last operation there was sudden pura ant tingling of the ends of the fingers of her left hand two day. Inter the skin of the hand an ingners began to change color then dry gangeres of the fingers and if the end of the thumb developed, if it physician hold her that he found signal in her than the state of the state of the state of the during the past month. The patient was in a very feetble and run-down condition on a dimission to the

convulsion which lasted fifteen minutes the pulse became imperceptible, and at 11 am, the child died. Much to my regret we were unable to obtain a post mortem examination but from pest experience, I have not the slightest doubt, that this was an othentic case of heatstroke.

At this point at is only proper to call at tention to the fact, that during the first half of September 1915. New York City was soffering from a heat wave of oursual length and severity September 10 in particular is featured by the New York Sum as being almost the bottest day of the year.

On the same day I was Invited by Dr Eli Moschcowitz, Pathologist to Beth Israel Hospital, to witness the autopsies of two patients who died with unexplained high post-operative temperatures. The autopsy did not reveal anything unusual, and certainly nothing to explain the high temperatures it was the pathologist's opinion, that both patients died of post-operative heatstroke. I am greatly indebted to Dr Harry E Isaaca, Attending Surgeon to Beth Israel Hospital, for his permission to incorporate a brief hustory of these two cases.

Carr lie R ag 38 was admitted September 6, 1915 During the precoding six years the patient had been suffering from frequent statels of pain in the right humber region, which redisted downward and inward. Larely similar attacks occurred upon the left side also for two days prior to his admission to the hospital, the patient womited very frequently and his bowels moved only with the side of the company of the side of the contract of the contrac

On physical examination there was elicited tenderness on deep pressure over the entire abdomen parti ularly marked in the vicinity of the umbilicus. In other respects the physical examination was of

no importance.

The patient was operated upon by Dr. Isaacs. September 8, at 5 pm. Abdominal indison was mad through the left rectus, five lacker in length. The omentum was adherent to the signoid flexure. O separating the adhesions the omentum was found to contain an abscess this portion of it was therefore resected and a cigarette drain was inserted to the signoid flexure. The wound was closed in layers.

Even before the operation the patient had been ranning a temperature up to ou? F therefore a post operature rise to o; F on the following morning was not ery supprising However, burning an intercurrent drop of two and one-half degree for a few hours in the alternoon, the temperature contine dt or ine reaching 10.75 F at 6 pm. of the following day and shortly thereafter the patient died (Chart?)

A careful autops, was performed a few hours later and following anatomical diagnosis established Chronic congestion of lungs, with acute hypostass chronic congestion of liver chronic congestion of spieen chronic congestion of spieen chronic in the region of the sigmoid flexure. In the absence of any findings explanatory of the high temperature, the pathologist arrived at the diagnosis of post-operative beat stroke.

Cast 3. Guale G age to was admitted September 6, 10 g, 10 Beth Iarsel Hospital. Patlent was operated upon one year ago for cheldithiasis notled bowers was obtained on the co trary the operation was followed by jamellee which had not extincted before. Operation September 8 to 15, by Dr. H. E. Isasca. Exposure of the common dust to upd a few inch in judgical incident in the right hypochondrium. Enormous adhesions were encountered, which made the exposure of the duct somewhat tedlous. The common dust was found to be distended and to contain several calculi after incision of the d ct these were removed. Drainage by two to be, one leading into the bepatic dust and the second into the common duct toward the papilla of Vater.

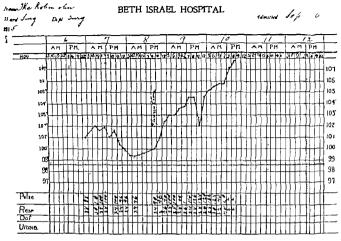

Chart : Case 2

After the operation the temperature began to rise slowly but steadily it reached rog F next morning rog F in the evening rog 6° F next morning and a few hours later the patient died with a tem perature of rog 8° F (Chart 3)

An autopsy was held on the same day and the following anatomical diagnosis was made by the pathologist Recent choledochostomy with recent localized pentonitis brown pigmentation of the myocardium chronic congestion of the liver with fatty infiltration acute hyperplasia of the spleen chronic pancreatitis chronic congestion of the kild neys with parenchymatous nephritis

In view of these findings and in view of the fact that the patient died thirty six hours after operation with a temperature of $100\,$ geV for the variable pathologists opinion that the cause of death was heatstroke.

I have been on active summer service at Mount Sinai Hospital regularly every year from 1899 to 1914 and have often had the impression that during particularly hot weather some of my patients suffered from a mild insolation however I find in my his tones only the following case reported as an

actual and undoubted case of post-operative heatstroke

CASE 4 Benjamin A Russian age 34 was ad mitted to Mount Sind Hospital August 7 1990 His principal complaints were cyanosis and pain of the foot he has had a number of intractable ulcers in the vicinity of the toes, resulting progressively in their total loss. He was treated at that time for Raymand 8 disease but there is no doubt that he was suffering from what we now designate as throm bo-angilita obliterans.

The pain was so severe that I finally acceded to the wishes of the patient and consented to amputate the lex. Amputation August 11 1000 through the knee Joint by the Ssabanjeff method. The patient did not react well from the operation and he was also noisier than usual. One and one half hours after operation the temperature rose to 104 F four hours later the temperature was 108 2 F. The patient was in a superous condition the skin was hot and dry. Insolation was suspected therefore an ice pack was ordered. The pulse be came imperceptible and was apparently unin fluenced by active stimulation. The patient died seven hours and forty minutes after operation with a temperature of 106 §? I Chart 4).

Autopsy twenty hours post mortem showed all

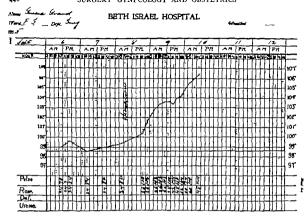

Chart 1 Cam 1

the organs normal with the exception of chronic parenchymatous nephtitis of alight degree Examination of the brail aboved a marked congestion of the vessels upon the surface of the brain. Somincrease of the cerebrosphan findle, with dilutation of both renticles. Cut acction of the brain aboved a congestion of the vessels. The sinuses of the dura were found to be normal. At that tim we looked upon these findings, as distinctly corroborative; four diagnosis of post-operative heatstroke

The summer of 1900 must have been a particularly severe one as regards heat and humidity because the only medical arti le published with post-operative heatstroke as its subject dates back to that year I refer to Gibson (1) who reports two cases of post operative heatstroke which occurred during the preceding summer in his service at St Lukes Hospital. The history of these two cases is the following

Case 5 Walter O C ago 8 was dmitted June 1 9 0, with an attack of appendicitis of moderate severity Temperature 2 F pulse 20 Immediat operation in gas and ether anesthesia

gangrinous appendix was found and extinpated gause designag partial mutro of wound Immedial recovery was good until the afternoon of the next day when the symptoms were such as to cause the gravest anxiety. The temperature was offered and very poor countenance plunched color asby grey-blu alin hot and dry some delimin. The roodition I the wound was perfect the control of the wound was perfect the production of the wond was perfect the production of the wond was perfect the production of the wond was followed by a refreshing sleep. The case thereafte terminated in a peount convoluence, CARE & Chales An E. was admitted to St.

Luk Hospital with an acute poperdicitle. The potient was extremely obese weighing more than three bundred pounds. Heart citon feeble and intermittent Temperature, ou.4 F Immediate operation evacuatio and drainage of a huge beaces, and estimation of gangereous appendix. One and one half hours after operation the temperature route to to 8. F the packs and an ice coil to the abdomen and head brought the temperature down to 1.6 F therefore the temperature fluctuated between 1.0 F and 1. F and was ery probably due to absorptio from the abscess or ity. Two weeks later the patients of the p

Gib-on read the paper at a meeting of the Surgical Section of the New York Academy of Medicine November 1 1900. The paper as reported in the Journal of the Inners of Medical Issociations created considerable discussion as is evidenced by the following additional case reports.

CASES 8 and o Johnson report a case in a child, of excision of a cicatins from the lower lip with a single skin graft. The temperature of the operating room on that particular day was to F Within a few hours after the operation the tem perature of the child rose to ros. F death occurred the same night. A few days later Johnson had two similar cases but this time prompt treatment with ice picks was instituted and was followed by recovery.

Case 10 Brewer reported a case of extrapation of the tonsil for arcoma. The temperature of the parting from was 00 F. Two hour after operation the temperature of the patient rose to 105 F and the pulse to 150. There was also debrum Prompt treatment with 1 e pa ks was followed by recovery.

Crandon and Ehrentried () tate that they have seen three cases of po-t-operative heat or sunstroke. The history of the following cale only is given

CASE 11 BOy 23, ears of age was admitted with an acute appendicitis of three dars duration. Tem perature 103 F pulse 1 o The street temperature in Boston on that day was 100-101 F with excessive humidity. Immediate operation a gain grenous appendix with a large abscess was found. The condition of the patient was very good on leaving the operating table. One hour later however three was a sudden rise of the temperature to 10 F and the pulse to 100. The skin was dry and red the tongue and lips were dry. The eves were gistening the patient was irrational. Ice pa is brought the temperature down to 100 F in twenty four hours thereafter convalescence was normal

I am indebted to Dr. Cunnific for the history of the following unpublished case of post-operative heatstroke

CASE 12 Miss C while visiting in the country was suddenly seized with sever general abdominal pains which soon became localized in the right liac fosts. Six hours later she was seen by her physician who diagnosticated an acute appendicates and referred the patient to Dr Cunniffe for immediate operation. The patient was transferred to a sanitarium, a distance of eight miles in an open automobile without adequate protection from the sun, on July 4 one of the hottest days of the sum mer of sigit.

900, December op 685.

The patient was operated upon at fight must altr in isson was made. On in sing the pentoneum a mail amount or servus fluid was found a swollen and onserted appendix was exturp ted the wound was losed without drainage. The patient was returned to her room at 140 pm. in good ondition. Two hours later the temperature of the patient rose to 100 S. F. A diagnosis of heat troke was made and prompt treatment with 1 e. pack incitited. The temperature remained erry high throughout that might. On the following days it rained from 101 to 10. F. and did no reach the normal until Jul. o. The wound healed by perfect primary union.

(h rt + 1 - < +

The literature dealing with the vimptom complex caused by exposure either to the direct ray of the sun or to high degrees of artificial heat is exceedingly voluminous. The references appended to Steinhauser's monograph Verensistem und Insolution' cover over twenty two closely printed pages and in addition the statement is also found that only the newer literature approximately that after 1850 has been con-idered. However, even with such a wealth of material

Berlin, Aug. Hurchwald

there exists no unanimity regarding the disease. After a very careful study of the more important contributions to the subfect I have arrived at the conclusion that our knowledge as to the etiology symptomatology pathology and treatment of the disease is in a chaotic state. If this is true of heatstroke or sunstroke in a general sense a disease so common as to be at times epidemic or endemic in nature, how much more likely is it to be true of that small and selected group which particularly interests us at present, namely post-operative heat or sunstroke Altogether as is seen, there have been reported in the literature only the two cases of Gibson a few more were mentioned in the discussion of Gibson's paper Three addi tional cases were mentioned casually in a textbook dealing with post-operative treat ment. Thanks to the courtesy of my col leagues, and from my own experience I am able to add five more cases. In other words. a total of barely twelve cases scattered through more than fifteen years, is all that is available for study. My personal experience is limited to two positive cases and a third doubtful one certainly an insufficient number to entitle me to discuss authoritively the many most problems, where others with a wealth of material have failed and vet even with this limited material, I have gained certain well founded impressions which I consider worthy of record

The most profife contributors to the subject of insolation have been the military and naval surgeons of the United States, Great Britain and Germany All of these, as well as the dvillan recorders of certain large epidemics in New York, Philadelphia, and Boston appear to be agreed that there exist various forms of insolation. All writers differentiate clinically at least two forms, namely sun or heat-stroke and heat prostration. a few authors describe also a third form, "beat enhanced".

As near as I can gather from the observations of the best authorities sunstroke is characterized by the following more important attributes, in addition to other less important, or secondary attributes. There is always a history of direct emosure to the sun and of

an abright onset, with complete loss of consciousness. The interument is, as a rule, hot and dry and flushed The body temperature is very high the pulse is full and of high tension. On the other hand in heat prostration these symptoms are either lacking or their exact antithesis is present. Thus we find that there is no history of direct exposure to the sun but on the contrary a history of being confined in a close, poorly ventilated room, and perhaps of exposure to artificial heat. The best examples of this form of insolation occur in stokers on steamers, and may occur even when the outside tempera ture is far below what is usually termed hot The onset is gradual and consciousness is usually retained. The skin is not hot, dry and flushed, but on the contrary is cold clammy and pale The temperature in these cases is variable it may be either normal or subnormal or may even be elevated but in instances of the latter it never attains the height it attains in cases of sunstroke, rarely going over 101° F The pulse, in contradistinction to the former is weak and thready Let us now see how far cases of post-opera

Let us now see how far cases of post-operative insolation correspond to these regulrements.

If we except the case of Dr Cunnife the case that on the day of the operation rode to the sanitanum in an open automobile, inadequately protected from the rays of the sun all of the cases reported had been sick either at home or in a hospital for a number of days prior to the operation and were therefore at no time exposed directly to the sun Assuming now that the symptomatol logy previously discussed is correct, it should follow also that cases of post-operative in solation are not cases of heatstroke but of heat prostration.

Nothing dennite can be sud regarding the rate of onset of the disease because all cases of post-operative insolation were operated upon in general anaesthesis therefore the rapidity of the onset, or the lack of it cannot be estimated at its true value. By the time the patient has fully rearted from the anæsthesia, the disease may already be fur ad vanced, or it may have just begun.

In most of the cases in which the integu

ment is mentioned at all we find it stated that the skin of the patient was very hot and dry in one or two a peculiar cyanosis is mentioned. This therefore would be a sym tom which is certainly more characteristic of heatstroke than of heat prostration.

I fear that not much reliance can be placed upon the quality character or rate of the pulse. Soon after an annesthesia with its complicating nausea and vomiting the rate and character of the pulse is apt to vary to such an extent, as to detract from its value.

as a differentiating guide

In all of the reported cases however we find it emphasized that the body temperature was extraordinarily high we thus find recorded the following temperatures 100 108 2 108 2 108° 107 106 8° 105 and 104 as a matter of fact it might be said that it is practically only upon the presence of these excessively high temperatures and even in the absence of any or all symptoms, that the diagnosis of post operative insolation has usually been made. The registration of the temperature by a thermometer is so exact and so absolutely uninfluenced by the per sonal equation of the observer that we must look upon it as absolutely reliable in every respect Judging from the high temperature alone it would follow that all of the cases hitherto observed or recorded belong in the group of heatstroke and not heat prostra tion

Almost involuntarily however there arises the question as to whether the above con clusion that all cases of post operative insola tion are cases of heatstroke and not of heat prostration and it is a justifiable one me for the sake of argument mention the following hypothetical case A patient 15 operated upon let us say for an acute gan grenous appendicitis with abscess six hours after operation the temperature may be either normal subnormal or slightly elevated the skin is cold clammy and pale the pulse is weak and thready and finally let us assume that this operation took place on a hot July or August day Upon the following day the condition either persists or it is already improved Ultimately the case recovers with out any sequelæ or the case dies within the tirst forty-eight hours. There is not a surgeon who has not seen such cases. No one ever thinks of making any other diagnosis than that of mild post-operative shock or ordinary rather severe post-operative reaction, and yet are not the hypothetical symptoms just enumerated, and the history and course characteristic of so-called heat prostration? I wonder how frequently these cases are over looked is it not probable that this is the most frequent form of post operative insolation more particularly as it is the form which is more likely to occur in the absence of direct exposure to the sun?

It is not at all remarkable that the few cases of post operative insolation have been recorded in two cities only namely Boston and New York As I believe these two cities with the addition of Ihiladelphia record also the greatest number of endemic or endemic heat prostrations. I do not suppose that there is anything in the geographical location of these cities to account for the greater frequency as even the larger cities further south with presumably higher tem peratures fail to report as many cases in proportion. It is perhaps possible to ac count for the greater frequency of heatstroke in these three cities by the fact that they are more compactly built up and that it is in these cities only that many of the inhabitants live crowded together in tenements

Trivial as it may appear I believe a second important reason for the greater frequency of heat prostration in these cities is to be looked for in the fact that their population has not as yet learned to dress properly during the summer. I believe in fact I know that most of the people wear too much too heavy too dark and too woolly clothing and I am also convinced that all of these are conducive to the production of heat insolation.

I also believe that the suggestions just made have an important bearing on the question of the production of post-operative heatstroke. The real hot days of the year are in the very smallest minority in New York City the great majority of the days of the year are either cold or verge at least upon coolness. On this account surgeons have learned to fear so much the occurrence of learned to fear so much the occurrence of

post-operative pneumonia that thes try to avoid it by instructing their nursing staff to be sure to cover the patient well in the operating room upon the transport to and from the operating room and upon the ar nval in bed. This has become a sort of fetish and an involabile rull. I have not the slight est doubt that this needless superheating of the patient is conducive in a great measure, to the occurrence of post-operative insolution

It was my intention to fortify my stand point regarding post-operative heatstroke by quoting the unusually high temperatures of New York City on those particular dates. In this however I was doomed to disappoint ment I consulted the files of the New York Sun upon the four dates upon which cases of post-operative insolation are known to have occurred and was rather surprised to find that with the exception of September 10 1915 on which a temperature of 90 F was recorded the temperature on the other dates was considerably below that namely 83 F June 1 1900 89 F Aug 7 1900 and 83 F July 4 1912 A little reflection soon convinced me of my error. It was well known to me that the deleterious effects of the heat are due not so much to the excessive height of the temperature on a particular date but more to a long continued term of fairly high temperature with a very high percentage of humidity and absence of any breeze in other words what is commonly heat wave. The longer the at mornheric conditions just described exist, the greater will be the number of heat prostrations. When I again consulted the files of the daily press upon the dates mentioned from this viewpoint, I found just the conditions described and also that they had been in existence for some time preceding that date.

TREATMONT

Whenever the atmospheric conditions are favorable for the production of insolation, all operating room activities should cease with the exception of those of an urgent nature It is quite within the range of possibility that insolation may occur even in a non-operated individual but the exhaustion dependent upon the operation is lacking and may be just the factor which determines the occurrent insolation and the success or fallure of treatment instituted

In all cases operated upon during a wave, the greatest regard should be hat the comforts of the patient. As alreaddated all the needless swathing in blar and hot water bottles is to be prohib. On the contrary at such times coolness the lightest of covers are indicated. Mins are also in order and desirable. Condriks should be permitted much earlier is generally the custom after operations.

It has already been pointed out that far only that particular form of insola which is characterized by very high tem tures and which is called heatstroke been recognized as a post-operative c pilcation. This is perhaps due to a lac our diagnostic accumen as it is quite pose that the second variety or heat prostrati so called, is the more frequent. While etiological factor appears to be identicated by the differ widely in their symptotology and what is of the greatest importation in the therapy

In heatstroke the temperature is so I that every effort should be made to reducand to nihilize its deleterious effects. fortunately we cannot avail ourselves in ti cases of the antipyretic properties of coal tar products on account of their depr ing effect upon the heart. Recourse must had therefore to physical measures to duce the temperatures. The best of the is hydrotherapy properly executed and can out in the form of sponge baths with a water An ice cap applied to the head not only grateful to the patient, but materia andsts in reducing the temperature and combating the debrium of the patle Enemata or Murphy infusions with ice was coming into contact with a large volume the superheated blood should also be tra and will also be followed by success. T form of treatment would, on the other ha be entirely contra indicated in that variof insolation which we call heat prostrati In this form the temperature is not only : elevated, but in many cases is even subnorn The exact opposite form of treatment therefore indicated namely the patient should be well covered and surrounded by hot water bottles subcutaneous or intravenous saline infusions, or warm rectal infusions are in dicated.

The rate and quality of the pulse is to be controlled and forms a valuable guide as to the character and amount of stimulation called for

In a certain number of cases of insolation

there has been found a peculiar degeneration of the blood which manifests itself by a laking. This suggests the possibility of venesection and blood transfusion provided a suitable donor can be found at short notice.

PERFORATION IN TYPHOID FEVER

WITH REPORT OF A CASE ASSOCIATED WITH ACUTE TAPHOID APPENDICITIS IN A CHILD AGED 7 RECOVERY!

BY IRVING H EDDY M D CHICAGO Instructor in Gyracology College of Medicine U eric y of Illinois

In discussing this most important topic of surgery one cannot refrain from praising the courage of the early workers in this field. In 1884 won Leyden first proposed to treat the resulting peritorities of typhoid fever through operative measures and at that time said.

I cannot longer forbear mentioning something I have for a long time had in mand namely whether or not it is possible to treat peritonitis by operative measures. The idea is rational enough when one considers that suppurative peritonius is very similar to suppurative pleintis

Further he says

But I must leave it to the surgeons to determine whether it is possible to accomplish anything by operation in this condition, but one thing is certain, it seems to me that herein lies a most fruitful field for investigation.

During the same year appeared an article by the renowned Mikulicz in which he reported three cases of pentionits treated sur gically and there is little doubt that one of them was a perforated typhoid ulcer While there is some doubt as to the authenticity of this case there is no doubt that Mikulicz's great teaching encouraged the surgical treat ment of pentionits

Lucke and Kussmaul however seem to receive the credit of being the first to have operated on and reported an authenticated case of perforation. During the same year Bontecou reported a case. To Professor J. C. Wilson in 1886, is given the credit of being the first writer on the subject in the English literature and at that time he made the following statement.

Granted that the chances of a successful issue are against you that the lesion of the gut may be very extensive that the vital forces are at a low ebb nevertheless the courage to perform it will come of the knowledge that the only alternative is the pations death.

As early as 1762 A G Richter of Vienna suggested the advisability of draining the peritoneal cavity for suppurative peritomits. Among early writers on the subject especially are to be mentioned Keen Cushing Finney Van Hook and others. In 1898 Keen published his extensive monograph Surgical Complications and Sequels of Typhoid Fever in which he reported a collection of 83 cases from the literature and in 1899 collected 75 additional cases making a total of 158 cases operated on with a mortality of 76 59 per cent the mortality of non-operative cases being quoted by Murchison as 95 per cent At this time Keen made the following statement

Read before the Chicago M Read Society April, 9 6.

The earlier the moment at which the operation can be done after the immediate shock of the per foration (provided, of course, there has been any as is sometimes not the case) the better it will be for the patient, every hour thereafter counts, since the infection of the peritoneum becomes more diffuse and intense.

In discussing the above, Cushing made the following reply

It is hard to understand Dr. Keen's advocating delay until symptoms of shock have passed away and his preference of the second treflee hours for operating when one appreciates that extravasation perhaps of virulent organisms is with all probability continuously taking place while we are waiting.

In Keen's statistics in which the time was given before operation the results were as follows

	No of	Der	Exer Ord
Operated on during first hours	36	£ g	7
Operated on during second hours. Operated on after 44 hours	83	65	8

FREQUENCY OF PERFORATION FOUND AT

The frequency of perforation varies greatly as is shown by the following statistics of various epidemics

In a series of regautopeles at Johns Hopkins Hospital perioration was found in 30 cases and occurred more frequently in ulcers with adherent aloughs. In Munich, in a series of 2000 autopaes, perforation occurred in 57 per cent.

Anther	Autopean	Percentage

Various Landon haspitals (From English, French and German Sources

The United States census reports of 1900 give the total deaths from typhold fever as 35 379. As 12 per cent of the total death rate is shown to be due to perforation there died during that year in the United States 4.22 from perforation of the bowel.

TIME OF PERFORATION

Finney analyzed 112 cases with 66 perfora tions occurring as follows

so during the second week,
16 during the third week.

o during the fourth week. The shortest period was four days.

In 193 cases Fitz found that perforation occurred in 88 cases during the second and third weeks, while 90 per cent of the remain der occurred during the fourth fifth, and sixth weeks.

Perforation is more frequent in men than women, which is explained perhaps partly by man s mode of living the late observation of many cases and their impatience during convalescence.

The fact must be borne in mind that per foration may take place at any period of the disease and every patient should be carefully guarded

SYMPTOMS

This grave complication occurs suddenly and very frequently unexpectedly however it may be preceded by increased abdominal distention, colicky pain borborygmus diar rhota, or haemorrhage may be the warming sign. Six cases of hermorrhage preceded so cases of perforation at Johns Hopkins Hospital

At the time of perforation the patient (if mentally alert) is selized with a severe pain of rapid progressing intensity greatly in creased by respiration passive or active motion and usually on palpation the greatest point of tenderness will be found in the region of the fleocacal valve

Pain in typboid fever was studied by McCres in 500 cases at Johns Hopkins Hoppital. He found that about 40 per cent of the cases are free from both pain and tender ness and rather less than 20 per cent have tenderness. It was most constantly present with perforation usually sudden in onset severe in character and paroxyamal in occurrence. Associated with pain are retching and vomiting the abdomen becomes progressively distended the walls become smooth and glistening respiration thoracic, and the paresis of the muscular layer of the intesting attains a high degree. The vomiting may become feed in character and even suggest obstruction or ileus. The features assume a hypocratic expression the nose pinched the extremities cold and the face and body overed with a cold clammy perspiration. The pulse increases in rate becomes quite compressible and offitimes thready

The blood pressure was carefully studied by Crile and Sheppard. Crile found the highest systolic pressure in uncomplicated cases and with normal arteries as measured to a Riva Rocci sohygmomanometer in 115 cases of typhoid iever 138 mm. and the lowest 74 mm. The mean during the first week was 115 second week 100 first week of ourth week 60 and the fifth week 68 mm. The mean pressure of all the typhoid was 104 mm. In 20 cases of acute pentoutis recorded by the same observer with the same instrument and otherwise similar cases the highest was 208 mm, and the lowest 156 the mean 166 mm.

In 5 cases diagnosed as typhoid perforation in which pressure determinations were made (4 of these verified by operation or autopsy one case not operated on) the pressure rose from 116 to 190 mm. during a period of four hours The second case a lad of 12 years admitted with general peritonitis pressure 105 Widal positive immediate operation later abdominal symptoms of peritonitis disappeared and the pressure fell to 80 mm. On the eighth day infection passed through the wall and peritonitis developed the pressure again rising promptly from 84 to 110 In the third case a slow perforation the pressure rose from 116 to 165 in two hours The fourth case a physician entered the hospital with general peritonitis and blood pressure 165 No operation was per formed Autopsy disclosed perforation vious pressure unknown A fifth case ty phoid had pressure of 208 At operation perforation and diffuse peritonitis were found

Sheppard s observation of 41 cases of typhoid fever near and during the fourth week, showed an average of 98 mm. The cases tabulated above, showing the various symptoms were reported by him and from them he deduced the following conclusions.

The pulse rate rises in almost all cases

The blood pressure rises in most cases but may be difficult to obtain owing to extreme restlessness. Hæmorrhage occurring simul taneously may greatly alter the blood pressure. Signs are most marked two hours after perforation and the blood pressure falls to the original level as rapidly as it rises. Sheppard also made blood pressure observations in the presence of distemtion pain increased leucocytosis and pulse rate and found no change except in one case of bronchitis. His final deduction is that a sudden rise in blood pressure is positive evidence of perforation while an unchanged pressure is not of negative value.

In the majority of cases there is an immediate elevation of temperature which in a very few hours is followed by a rapid fall Rigidity and muscular spasms are not usually present to a marked degree immediately after rupture. Chill is rather a common symptom and is often followed by a cold perspiration. Leucocy tosis is a very important symptom but to be of the highest value the blood picture must be studied frequently during the course of the disease.

Considerable importance has been given to

the disappearance of liver dulness as a symptom of perforation by some writers while others discredit it by stating it to be comparatively rure

The Widal reaction should be taken re peatedly in all suspicious cases of typhoid and will be of the utmost value it previously positive in a suspected case of perforation

Hiccough if present is an important symptom because of its infrequency during the normal course of the disease and every patient should be examined also for the presence of the free fluid in abdominal cavity as a variable quantity may be present from the escape of liquid contents

DIAGNOSIS

In arriving at a diagnosis a definite dis tinction should be made between the symptoms of immediate perforation and those due to the peritonius resulting therefrom Unless this all important distinction is thoroughly recognized we have deprived our patient of his chances of recovery The attending phy sician must ever be on the alert in every case or suspicious case of typhoid to accomplish this distinction and the nurse or house physician in charge should be instructed to notify him immediately of any change in the symptomatology or condition of the patient To be able to arrive at the proper conclusion one must especially have a clear clinical picture of the following conditions before him acute appendicitis hemorrhage ileus acute intestinal obstruction acute pelvic infections acute cholecystitis or cholelith

The diagnosis of acute appendicitis in most cases is comparatively easy. Too much stress cannot be emphasized in taking the history of every case offering difficulty in diagnosis when properly elicited if the patient be of moderate intelligence much valuable information can be obtained that will assist us narriving at a proper conclusion. The pain of appendicitis not infrequently beginning in the epigastrium radiating over the entire abdomen greatly relieved for a time after the stomach has been emptied of its contents by vomiting followed by localized tenderness and rigidity over Burney's point

absence of a Widal and with comparatively little disturbance of the pulse and temperature curve minus shock, will rule out appendicuts.

Of 717 cases treated at the Montreal General Hospital harmorrhage occurred in to per cent. In harmorrhage if severe, the pulse becomes rapid and compressible the blood pressure falls, the skin acquires a wary pallor there is lividity and coldness of the limbs, the temperature is subnormal, and little or no paln. This presents a clinical picture that cannot be misconstruct.

In ileus or intestinal obstruction we not infrequently have a history of an inflamma tory condition the presence of possibly strangulated hernia, or of a previous operation.

The first symptom to appear is a severe griping pain more or less localized paroxysmal in character The peristaltic wave can frequently be seen ending abruptly and, if obstruction is incomplete fluids and flatus may be forced through with a gurgling sound or if complete, obstinate constinution nauses, and vomiting are early and distressing symptoms. At first the normal stomach contents are elected but soon this is followed by bile. derk fluids and later intestinal contents with fescal odor The abdomen at first flaccid, soon becomes tympanitic the pulse increases rapid ly becomes more or less thready the temperature may be subnormal and the patient presents the general picture of collapse however the symptoms as a whole develop less rapidly than do those of perforation

The pain of pelvic lesions is usually more continuous, but not so severe except, perhapa, that of extra uterine pregnancy Vomiting is not frequent in these conditions. The not infrequent bilateral condition, the tenderness and rigidity obtained by double palpation. the presence of times of a mass in the pelvis associated with tenderness and rigidity of the vaginal vault, will easily rule out pelvic lesions of an inflammatory character while if we suspect extra uterine pregnancy the early signs of pregnancy collapse, associated with subnormal temperature absence of leucocytosis, the presence of uterine hæmor rhage and a fluctuating mass in the tuboovarian region will be valuable aids.

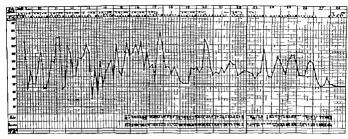

The not uncommon association of gall bladder infections and typhoid fever calls for special consideration A study of the liters ture shows that perforation is rather infre quent after 40 years of age while on the other hand gall bladder infections are relatively infrequent before. It is more common in females than males and emecially in those who have borne children The attack is fre quently associated with indiscretion in diet. coming on suddenly with severe paroxysmal pain in the epigastrium and right hypochon dric regions Repeated vomiting is the rule and the contents are usually richly bile stained The abdomen is distended and rigid but the greatest point of tenderness is usually at the costal margin. The tempera ture rises while the pulse is comparatively slow which is an extremely important diag nostic point A study of the literature demonstrates that perforation of the gall bladder in typhoid fever does occur and issues a warning sign to be on our guard.

Finally if our cases are studied carefully and the conditions that are likely to cause confusion kept closely in mind, few mistakes will be made, and many lives sayed.

TREATMENT

There is only one method of treatment in these cases requiring discussion which was well stated by Mikulicz in 1884, when he said If susplicious of perforation one should not wait for an exact diagnosis and for peritonuts to reach a profound degree, but, on the contrary one should immediately proceed to an exploratory operation which in any case is free from danger. How much more true the above statement is in present day surgery is well understood. Our patient's life depends on the recognition of the perforation, and not the resulting peritonitis, and unless we are capable of doing this we are a stumbling block to the nations welfare.

As soon as perforation is recognized or greatly suspected the patient should be given morphine immediately Quoting Morris We are choosing the lesser of two evils, for the tremendous shock is more deadly than are the escaping bacteria when the patient is not quieted by opium.

Temperature chart. Case C. H. Note sudden rise of pulse and temperature on the r th at time of perf. attorn

There seems to be a difference of opinion as to the choice of anasthesia Wookey believes these cases take gas and either well. In two cases reported by him cocaine was used satisfactorily for exploration but retraction of the edges and the necessary handling of the inflamed bowel were painful and this together with the realization of being subjected to an operation cause more shock than general anaesthesia.

As to choice of incision most surgeons will agree on the right rectus or McBurney a as statistics conclusively show that more than 80 per cent of the cases perforate in the lower eighteen inches of the ilcum and the nearer we are to the lateral wall, the less the danger of spreading the infection over the peritoneal cavity. The perforation should be located as quickly as possible and with little handling of the bowel.

The perforation can be closed in most cases with a purse string reinforced with a row of Lembert or mattress sutures the greatest care being taken however not to constrict the lumen of the bowel which if done will almost certainly result in ileus. In all cases the ileum should be explored as far as the infiammatory process extends for multiple perforations or deep ulcers. Some cases may require resection where the perforation is large but unfortunately the quickly resulting peritoration and extreme shock of such an extensive procedure has proved fatal in nearly all reported cases of this character.

The peritoneal cavity hould be carefully sponged with value solution but irrigation should be avoided unless a general peritonities exists. Thorough drainage should be employed and the Fowler position obtained as soon as the patient's condition will permit.

Intravenous subcutaneous or proctoclysis should be used according to the demand of the condition of the patient. Morphine should be continued until the pentonitis becomes well localized and the bowel not disturbed in any way. Later they should be taken care of by flushing and small doses of eserine. No food whatever should be given by mouth and if comiting has been quite severe lavage should be used before the patient comes from under the anaesthetic Stimulation should be used according to the demands of the patient and the condition of the heart muscle carefully observed.

In conjunction with this paper I wish to present the following case

C H. age 7 Premous history Child showed some malnutrition during first year but rapidly outgrow it Had measles about two years ago and a few months later chicken pox and mumps, all of which were mild in character and left no sequelse otherwise has been exceptionally well

Present illness On August 28 1914 after return ing from a ride, he complained of headache, and the next few days seemed to have a cold which did not yield to the usual home remedies. He appeared languid and drowsy Dr J V Nicholson was called to see him September 9 and after a careful examination a diagnosis of bowel infection was made. The bowel movements were rather watery

and decidedly green in color. The patient had a variation of temperature from of to rock The following day the temperature varied from of to 101 and on the 11th 08.4 to 105" with continua

tion of the green movements.

No improvement was shown during the next few days and I was called in consultation the evening of the 15th. A careful examination was negative other than abdominal trouble. Much distention was present but no special tenderness, and the bowel movements were decidedly green. Until this time the child had been cared for by the mother. A nurse was put in charge of the patient and a Widal suggested if improvement did not occur immediately

On the 6th there was little change. The 17th. at 10 to a.m. temperature on 8 pulse on respira tion 28 4'30 p.m., temperatu e e4 pulse 130, respiration 28 and at 6 p.m. temperatu e o2 8° pulse 150 respiration 18. All movements of the day were recorded as very green and the result of normal saline flushings. 7:30 p.m. the child had a severe chill lasting to minutes which was followed by a very severe pain in the right side. The pulse became weak and the lips and fingers evanotic. The grave condition of the patient was recognized immediately by the nurse and Dr Nicholson was called. An immediate blood examination was made by Dr Nicholson showing a leucocytosis of \$2,000, and the patient was ordered to St. Joseph a Hospital. The temperature at 8 5 p.m. was 105.0° pulse 160 respiration 40 9.00 p.m. temperature 105° pulse 160, respiration 4 9.45 p.m., temperature 1 3.4 pulse 140 respiration 40. The patient entered the operating room at 1 to p.m. with the typical expression of collapse and peritonitis. I was assisted by Dr Nicholson, to whom I wish to give du credit for his alertness. A McBurney incision was made and the following conditions discovered

1 A very severe appendicitis appendectomy

A perforation about 16 inches from the fleocecal valve which was rapidly closed and two other ulcers that showed clearly through the peritoneal coat were reinforced. The abdominal cavity was carefully aponged with normal saline solution and a small median incision was made for counter drainage. The patient was returned to his room

tr. so a.m.

At 1'3 a.m. pulse 160, respiration 40. Stimu lants and morphine were given. At 7:00 a.m. axilia temperature 100 pulse 140, respiration 32 0.00 a.m. temperature 100 pulse 130 stronger respira tion 34. Digitalin 1 200 was given every 4 hours. 6:00 p.m. temperature o pulse 140 respiration, 8 r no m. temperature 99.6°, pulse, so respiration, s8—but very resiless. September 9 temperature varied on to 1 1 pulse, so to 146 very weak. September so, temperature varied o to o4.6°, pulse x28 t 52 Abdomen greatly dis-tended with marked intestinal paresis.

Eserine gr 200 given at 9 p.m. and 3 a.m. with calomel gr 1 so every hour 7:00 a.m. watery bowel movement and much gas. September 21 temperature 100 to 10 pulse 125 to 136 respiration as to 18 Escrine 4 to and 4 involuntary howel movement 2 30 p.m. and semicolid bowel move ment at 8 30 p.m. Positive Widal obtained. September 22 temperature 100 to 102 pulse 108 to 128 respiration 20 to 24 Fairly good night escrine at 8 2 and 8 September 23 temperature on 6 to 014 pulse, 100 to 13 September 24 99.6 to 03.4 pulse, 100 to 13 September 24 temperature 99.8 to 102.6 pulse 104 to 128 Sept. as temperature 100. to 1 2.6° pulse 120 to 128 September 26 temperature 99.4 to 101 pulse 111 8 Sentember 27 temperature o3.6 to 100° pulse 100 to 1 8 September 18, temperature 08 to 08 6 pulse 08- 1 September 19 and 30, tempera ture or to 08 6° pulse 96 to 08 Octobe tempera ture rectal of to 97 pulse 80 to on very ir regular acute myocarditis present. October 3 rectal

irregular Patient cold external heat applied Pulse remained very irregular during the next week In conclusion the following deductions may be drawn

temperature 96.4 to 97.4 pulse 64 to 88 very

after which time recovery was uneventful.

1 While perforation varies greatly in different epidemica, about per ent of the total death rate is due t this complication.

3 That perforation occurs in about 3 per cent of all cases treated.

That perforation is elati dy infrequent in children

4. Statistics show that over 80 per cent of the total perforations occur in the lower ileum.

5 That the location i perforation coincides with the study of Beer

6 That the majority of cases perforate during the second and third week.

7 Diarrhora is an important factor in its prod c tion.

8 Acut abdominal pain during the course of typhoid abould always be taken seriously

 The sudden rise of blood pressure is positive evidence of perforation while an unchanged pressure is not of negative value.

o. The importance of a careful study of the blood cannot be overestimated.

II The welfare of the patient depends on our ability to differentiate between the symptoms of perforation and those of the resulting peritonitis.

The treatment of perforation is surrical and the death-rat is in inverse ratio to the length of time allowed to clarge before operation.

3. Opiates are indicated as soon as perforation has taken place and should be contin ed until the peritonitis has become well localized.

RIBLIOGRAPHY

DELIVERY BY ABDOMINAL SECTION'

BY EDWARD P DAVIS M D FACS PHILADELPHIA

TOTHING has been more striking in the evolution of medical science than the advance which has taken place in a comparatively brief time in The establishment of obstetric surgery caesarean section upon a basis of success comparable with that of other abdominal operations was a great advance over the uncertain and unsatisfactory and difficult de livenes by forceps or craniotomy recently it was found that in addition to the problem of delivering the child safely a very considerable range of pathological conditions accompanying pregnancy may be success fully dealt with at the time of delivery The fact that it is difficult and often impos sible to positively know the condition of pel vic and abdominal organs without section and that during labor serious changes may occur in intra abdominal conditions which may result in infection or hæmorrhage has made delivery by abdominal section in many instances a far more complicated procedure than simple casarean section

Highly contracted pelvis has been made one of the simplest complications of parturition by the success of a classic cressrean section but pathological conditions in the pelvis and abdomen complicating pregnancy may be of several varieties.

The most senous accident in labor or in pregnancy is rupture of the uterus and wheth er this occurs during partunition or during pregnancy the most successful treatment is by abdominal section. Rarely is it possible to save the uterus. Hysterectomy in the great majority of cases is indicated and if it is thought wise to drain through the vagina, extirpation of the uterus may be chosen

Foc of infection in pelvic or abdominal organs developing during pregnancy may threaten the patient is life through the burst ing of an abscess and the escape of its contents into the peritoneal cavity. One of the difficulties in diagnosis in such a case is

the fact that such a focus may remain quies cent during the greater part of pregnancy and its existence only become apparent through some accident. In the experience of the writer a woman of unknown anteredents pas ed easily through a spontaneous labor and a puerperal period of two weeks without evident complications. During the third week while convalescent and acting as helper in a ward after lifting a bucket of coal she complained of vague indefinite abdominal pain. Influenza was epidemic at the time and many of her symptoms were those of Peritonitis rapidly developed and section undertaken too late revealed an old focus of infection in a tubal abscess which had ruptured upon exertion causing fatal infection Could the existence of this abscess have been known at the beginning of labor and abdominal section promptly per formed the patient's life might have been saved. It would have been wiser in that case to have delivered the child by section without labor and then dealt with the ab-

A not uncommon and very great risk to the parturient woman is appendicitis. If this condition is not met promptly by operation and abscess forms the uterus will usually undergo contraction and abortion or labor develop. In either event, the contractions of the uterus will rupture the wall of the appendiceal abscess and infection will follow The majority of obstetricians remove the diseased appendix at whatever period of pregnancy appendicates may develop and with excellent results. Should appendiceal abscess complicate gestation and viability it would be safer to open the abdomen empty and close the uterus and then deal with the appendiceal condition

Obstetricians have learned by experience that it is dangerous for a woman having a septic focus in pelvis or abdomen to undergo the disturbance of labor and there is no method combining prompt delivery and efficient

Read before the Medical and Cheurgical Faculty of Maryland, Baltimore, April 5, 916.

treatment of the septic condition present which compares with abdominal section

The presence of pelvic or abdominal tu mors complicating pregnancy is also an indica tion for section. Ovarian tumors during pregnancy have an especial tendency to twisting of the pedicle and the gangrenous changes in the tumor which follow this accident. Fibroid tumors which block the pelvis or seriously interfere with the contraction of the uterine muscle furnish a valid indication for section. Multiple fibroids of the uterine muscle which may produce no tumor large enough to be detected by palpa tion prevent the physiological development of labor and are best dealt with by delivery by Cancer of the cervix calls for the prompt extirpation of the uterus so soon as discovered, but if the patient be near viability and wishes to take the risk of the prolongation of preenancy to secure a living child delay may be practiced in accordance with the patient s request.

The topic receiving most attention at present from obstetricians throughout the principal clinics in this country and abroad is the treatment of advanced pregnancy complicated by premature separation of the placenta, whether normally altuated or placents previs. This topic was discussed at several international meetings just before the European War and in the literature of the year 1915 the number of papers upon this subject far exceeds those written upon any other topic. Obstetricians recognize fully the fact that many of these cases must be dealt with by the general practitioner in emergency Certain well-defined procedures are available under these dreumstances But as hospital facilities are becoming more abundant in this country and means of transportation more efficient, more of these cases will receive hospital care. Under these circumstances, there can be no question but that premature separation of the normally implanted placenta is dealt with most prompt ly and safely by section.

Obstetric opinion may be divided as to the choice between vagnal and abdominal section, but the writer's preference is decidedly for the latter. There is a much wider difference of opinion concerning the treatment of placenta prevua by abdominal section Many obstetricians limit the operation to those cases where the cervix is undulated and not rendlly dilatable and where mother and child are in good condition the child's heart sounds being sufficiently strong to indicate that it has not suffered greatly from the loss of maternal blood.

In the mind of the writer placenta pravia is analogous with ectopic gestation. By ectopic gestation as commonly understood, we mean the attachment of the ovum out side the cavity of the uterus, and the common acceptation of this term limits this attachment to the wall of the uterus and the contents of the pelvas or abdomen. Under these circumstances, the danger of infection aside from that which accompanies an operation is very little and anses from the proximity of the ectopic gestation to the intestine and its contents of foces and bacteria. The great risk of ectopic gestation is ordinarily harmor thage.

When placenta pravia is considered the ovum at all stages of pregnancy is attached very near the vagina, which invariably con tains bacteria. Dilatation of the cervix to some slight extent is inevitable and this is at once accompanied by the danger of infection This danger is now appreciated and the majority of obstetricians have aban doned in placenta pravia tamponing the vaging or other forms of treatment through the vagina, except such as have for their object the emptying of the uterus by the removal of its contents. In placenta prævia the lower portion of the uterus is unusually rich in blood and the separation of the pla centa opens many channels for infection. Post partum hemorrhage is a frequent ac companiment of vaginal delivery in placenta przevia.

Under these circumstances, in cases where the greater portion of the cervix is covered by placenta and the membranes are not readily available for rupture, it is the writer's belief that delivery by abdominal section is indicated

Modern surgery has reiterated anew the doctrine of the importance of shock. In all departments of surgery the effort is constantly made to improve anæsthesia and to block those channels by which dangerous reflexes may be conveyed to vital centers Obstetn cians recognize the fact that there are patients in whom the physiological phenomena of spontaneous parturation cannot be successful ly carried out and in whom the occurrence of uterine contraction and dilatation end in failure to deliver the child and in dangerous depression. The phrase physiological in competence for labor has been proposed by some who have written upon this subject Under these conditions anæsthesia and de livery by abdominal section at a most favor able time and under the most favorable cir cumstances give better results than a painful and tedious labor followed by difficult vaginal delivery and its inevitable traumatism

The present world crisis has considerably increased the value of human life through the enormous waste which war has occasioned Hence the preservation of infant life is at present a topic of widespread interest the ancient rule holds that the mother's interests should first be considered cases arise in which the mother's interests are not un duly jeopardized if the birth of the child be secured by abdominal delivery Patients who have lost children in previous labors through disproportion or physiological in competence although the pelvis may be of average size may rightfully elect delivery by section in the interest of the child. Were the mother only to be considered craniotomy might be employed in the failure of spon taneous labor

Very rarely condition arise where prompt delivery under anæsthesia is indicated in the interests of mother and child because some condition of visceral disease threatens the lives of both. In the writer's experience delivery by abdominal section in eclampia is very rarely indicated and yet occasionally where the mother has apparently been in good condition before the first convulsion and where the child's heart beats are strong and regular and no sign of labor develops immediate delivery by section may be admitted. In cases of scrious disease of the heart where the child is abundantly viable and compensa

tion is failing it may be possible to save the life of the child and prolong that of the mother by delivery by section without labor

Under what conditions shall delivery by abdominal section be terminated with the sterilization of the mother? A plain indication arises where there i abundant evidence that the uterus is the site of an active septumentection at the time of libor. In these cases a cardinal rule of operation calls for the removal of the fallopian tubes and body of the uterus and the leaving of the uterne stump outside the peritoneal cavity or if the operator prefers the extirpation of the entire uterus. The removal of the ovaries or their preservation must depend upon the age of the patient, and the condition of the polyic tis sues at the time of operation.

Shall the obstetrician at as judge in those unfortunate women who are hibituilly immoral diseased and mentally physically and morally degenerate—and shill the proceeding power of such be terminated by operation. In these cases the cardinal rule of the profession is to save life without regard to the moral character of the individual but in those women who are imbecile epileptic insane or degenerate the permission of parent or guardian should be obtained for sterilization. If such is not available consultation should certainly determine the propriety of the step.

Have husband and wife the right to decide that sterili-ation be performed?

This question may be a difficult one to de cide but in the experience of the writer such a request will rarely be made of the obstetric ian unless there is the history of previous unsuccessful and dangerous partuntion. Such is the success of repeated section that this choice should not be hastily made and if the parents are sound and there is every reason to believe that the offspring are healthy the claims of repeated section must be urged. But if the parents decline to take the risk of repeated section and request sterilization it is a question whether the obstetrician has a right to refuse such a request.

The Roman law which called for immediate section upon the body of a woman pregnant near term and dying suddenly to save the child still holds, and in the writer's observed ton three cases have ansen where this procedure was clearly indicated. Caution must be observed not to promise the ultimate survival of the child for in some of these cases the disease which ends the mother's life may render unpossible the continued life and growth of the infant. In abdominal or other ectopic pregnancy section is clearly indicated.

By whom shall delivery by abdominal section be performed?

The best results will be obtained when these operations are done in well-equipped maternity hospitals and by obstetridans Neither the general surgeon nor the gyne cologist has sufficient experience in pregnancy and parturition to make him a wise judge in deciding the important questions which these cases present. These patients call for far more than merely technical skill. A thorough knowledge of the pathology of pregnancy and labor not only in the mother but in the fortus, is necessary for an intelligent choice of the variety of operation and the time at which it should be performed Improvement in obstetric teaching and the development of maternity hospitals are gradually producing competent obstetricians, and such should deal with these cases.

It may not be without interest to allude briefly to the writers expenser. These cases came from an obstetre service in a large dly and were operated upon in a small maternity hospital where the facilities of operation while practically adequate, were not those of a lururiously appointed surgical ampatheatre. These cases cover a period during which obstetric surgery was developing in this country and therefore represent what may fairly be taken as an average

The indications for operation embraced the field of obstetric pathology outlined in

the preceding paragraphs.

The operations consisted of 129 classic cesarean sections 50 hysterectomes in which the stump was dropped and the abdomen closed without drainage 32 Porro operations in which the stump was fastened by a clamp

in the lower end of the abdominal incision a externations of the uterus, and 2 sections performed at the moment of maternal death - a total of 216 operations. These cases may again be divided into those that were in fair condition at the time of delivery with no fatal disease of the viscera and apparently uninfected by sensis, and those which were at the time of delivery injected or suffering from some fatal disease affecting the import ant viscera Of the former cases in good con dition, there were 151 with one maternal death - a maternal mortality rate of 0.066 Of those cases that were injected and in had condition there were 60 with 16 deaths - a mortality rate of 26 plus per cent, the mor tality of the entire series being 8 per cent.

The one case of death in those in good con dition occurred from peritoritis caused by the bacillas protein vulgaris. Bacteriological examination of suture material dressings, and instruments failed to disclose the source of in fection.

With the other fatal cases the toruemia of pregnancy in its various phases was the cause of death in by far the greater number of cases. Degenerative conditions of the heart muscle kidney and liver were the principal visceral lesions in these cases. Among those dying of infection the number was relatively but a small proportion of the whole and of these infections pulmonary infection by the pneumococcus or the mixed infection of catarrhal pneumonia and acute pulmonary tubercular infection were the principal causes of death.

These patients were many of them brought by ambulance from tenements and were in various stages of exhaustion and infection In many of them there was no time for adequate preparation. As regards the foctus there was no fotal mortality in any case in which the foctus was in good roudiilon at the time of operation and those foctal deaths which occurred were the result of previous attempts at delivery or infection or malformation. Of especial interest to the writer are twenty four cases of placenta prævia without a maternal death.

DIAPHRAGMATIC HERNIA

BY OTTO J SEIBERT M.D. CINTENATI ORID

If we carefully review the literature on diaphragmane herma we will readuly and that this condition is not nearly so rare as has heretofore been considered. A diaphragmantic herma has always been regarded as a surgical curiosity perhaps chiefly because the condition has rarely been diagnosticated prior to operation or post mortem examination. In a review of some 250 cross by Leichtenstein (1) in 1897 in only 5 caves was the diagnosis made before death.

If we consider the anatomical development of the diaphragm and the relation it bears to the abdomen and the viscera it will seem almost obvious that herma of this type should be just as common as other abdominal herma. The diagnosis has heretofore been difficult because of the lack of external manufestations and definite physical signs. It has frequently been found while operating for some entirely different cause but most often at necropsy where death may have been due to other causes or directly to the herma (i.e. strangulation or incarceration of the stomach or gut or to intrathorance pressure)

Diaphragmatic hernia may be divided into

three distinct types

True herma Those having a distinct sac These may be either congenital or traumatic False herma Those without a sac Most of these are traumatic

Ecntration This is not a hermia in the strict sense of the term but a doming or thinning out or the entire absence of a part

of the diaphragm.

In view of the pathology of this condition certain signs in the examination of the chest, such as displacement of the organs of the chest, dullness on percussion guigling etc should be of value in making a diagnosis especially in conjunction with the subjective symptoms. However these signs have on some occasions only confused and have led to other diagnoses such as pleuntic effusion O Dwyer (2) of New York in 1890 reported a case of this kind hinding a diaphragmatic

herma of the small bowel while operating supposedly for a pleunti cifu ion in a child '1' years old. The following day he operated for the cure of the hirma but the child died soon after the operation. In recent years however, the Nray has been the means of diagnosticating the condition prior to operation or aut pive and through it diaphragmatic herma will in the future. I believe become more and more a denute surgical condition, rather than remain a urgical currisity. A brick review of the literature of some of the more interesting cases or series of cases will I believe, not be aim.

As early as 1852 Mr. Lawrence (3) reported to the London Lathological Society a case of large eventration found at aut ip v on a man who had died of pneumonia In 1801 Hillier (4) reported to the same society a case of diaphragmatic hernia of the small intestine found at autop v in a child 312 years old that had died apparently from intrathoracic pressure. In the Bulletin of the Anatomical Society of Paris (5) for the year 1862 is found a report of a case in which autonsy showed that death had been due to strangulation of a diaphragmatic herma of the large bowel In 1907 Gordon (6) of British Columbia operated on a man 33 years old for what he thought was a pylonic stenosis and found the entire stomach in the chest-cavity A gastrojejunostomy was done after replacing the stomach in the abdomen death, however tollowed three days later No attempt was made to close the enlarged diaphragmatic opening In 1807 Cordier (7) of Kansas City did an emergency op eration for an acute bowel obstruction but was not able to locate the obstruction until after death at which time he found the entire stomach and large bowel strangulated in the chest-cavity through an opening in the dia phragm 3 inches in diameter. Death was caused by the strangulation In 1014 Binnie (8) stated that there were only two cases of cures on record

In 1915 Robert Kienboeck (9) presented a rather extensive classified review of the Ger man literature, which in brief is as follows

A. Cases where autopsy showed death to have been due to strangulation of bowel or stomach through displaining. There were 11 left sided false hernias 2 left-sided true hemias 1 left-sided rupture of the dia phrasm.

B Cases where autopsy showed death to be due to strangulation of stomach with perforation into (a) the thorax—3 left sided false hernias (b) the abdomen—1 left sided true bernia and 1 enlarged craophageal opening with pilit in disphragm.

C. Cases simulating gustric ulcer or pyloric stenosis. Death due to other causes Eight

false hernias and 2 true hernias.

D Cases diagnosticated intra vitam and confirmed at autorsy One eventration.

E. One case coming to operation with large opening in the diaphragm. Stomach par tially in the chest-cavity Reposition of stomach and closure of diaphragmatic opening resulting in clinical cure

Perhaps the most recent report of a cure of this interesting condition is that of Balfour (10) in January 1916 of a case from the Mayo Clinic, Rochester Minnesota. A ten tative diagnosis of hernia had been made prior to the \ ray examination and later confirmed by the X ray and this in turn at operation, at which time a radical cure was effected. This case was apparently of trau matic origin, trauma having taken place a years previously There was a large tear in the left half of the disphragm allowing the protrusion of both stomach and bowel into the chest-cavity causing the displacement of heart and lungs, giving rise to rather definite signs on chest examination.

The cases cited are perhaps only a small percentage of those already reported. How ever in a review even more extensive than the foregoing two facts remain prominent manely the extremely small number of cases recognized prior to autopay and the still smaller number of cures effected. Dia phragmatic hemia will no longer remain a surricial curiosity as heretofore but with the

A ray at hand will become an almost every day finding. For this reason the diaphragm will in the future become a more frequented field for the surgeon. Each case bears with it different points of interest and is there fore worthy of record. The history of a case, which I had occasion to operate upon early in December 1915 was of especial in terest from various points of view and is in high as follows.

Mrs D age 68 Family history ecalive. Previous personal hist ry Although she has had more or less stomach trouble all her life even in her early childhood she has never had any real severe illness and has enjoyed comparatively good health. She has had fou children and the confinement with each of these was a long protracted one the labor in each case lasting from 36 to 7 bours. From the first of these she dates her present trouble. This was about 36 years ago. From then on she began to have pain after eating with much discomfort belching and sour stomach. She often vomited her entire meal, undirested, four or five hours after ingestion. In the last two years this train of symptoms has become exaggerated in every respect. The pain and distress after eating became more severe sektom was she free from sour stomach or belching & miting followed almost every meal and the vomitus was often of a brown color. In the last year the poin and discomfort after eating became so severe and the vomiting so regular that she became afraid to ent, although she always had a good appetit. She has lost pproximately 35 pounds in weight in the last ten months.

On December 1 I advised her to con 10 the city for stomach analysis and V rey camination. The physical examination at this time showed little or cept signs of great loss of weight. Although still a large woman the akin was loose and diably. The heart and lungs were remain to association and percension. There was no displacement. Clinical disposits the time was prioric obstruction, in disposits the time was prioric obstruction, in the property of the control of the control of the arring been prepared for a barium meal, she was sent to Dr. Charles Gooman for X-ray examina

sent to Dr. Charles Gooman for V-ray examination. This proved to be most interesting Rpeated attempts to get a shadow of the bard in in the normal region of the stomant failed. However, shadows of the bardom in what ppeared to be the duodenum were shown, but these were rather far to the left. At last a large plate showed a large bloth of the bardom in its extreme upper portion and on close examination it was found to be above the shadow of the diaphragm. This gave D Gooman the idea that her trouble might be in the exophagus and not in the stomach. Fixtures through the chest were then taken. All of these showed what appeared to be the outlies of the stomach bove the

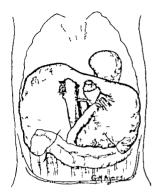

Fig. Showing the entire it main in the post milliand in the behind thin heart, and dense abrows band by ding the fill rus and first port. If the duodenum to the marge of the entarged desophageal opening.

diaphragm behin I the heart with the greater urvature upward and the pylorus to the left hoother examination two days later howed the same results. The stomach analysis proved to lenormal in every respect except for a faint trace of blood. This I think was due to the stomach tube which passed with difficulty after reaching a certain

On December 6 the abdomen was opened one inch to the left of the median line. firectly below the margan of the ribs and our \ ray diagnosis wa readily confirmed The duodenum was seen passing to the left and upward directly to an opening in the diaphragm large enough to admit the entire The opening was to the left and post nor and proved to be the ersophageal opening. The entire stomach was found in the posterior mediastinum directly behind the heart In attempt was made to deliver the organ through the opening into the abdominal cavity but this could not be done It was found that dense fibrous bands of adhesions were holding the pylorus directly to the margin of the ring. These bands were so dense and firm that they had to be cut. After this was done the stoma h could realily be pulled through into the abdomen. Interrupted sutures of heavy chromic catgut wer then passed through the margins of the ring so as to almost entirely close it. This was accomplished with great lifficulty bec use I the depth nd angle f the tiel I an I also because the mo e ments of the disphragm caused the liver onstantly to all over the ring but chiefly because f the

Fu. St. pl. through the berniaric aut. In us last had become find the much be ght. Into the multist

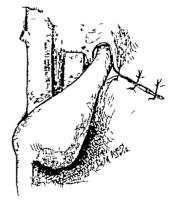

Fig. Str. ngted linkstentel ksn. thh salpang

Fig 4. Roentgenogram, touched) The stormen is teroposterior The stomach is t the left of the spine and ppears to form a loop before the polera is reached Just external to the pylorus is the shadow of the heart pe

proximity of the aorta on the one side and the pericardium on the other Bef re lod g the abdomen I fixed the st mach to the bedominal wall with two chromic gut sutures. The patient has made rather uneventf I recovery and since the fourth day after the operation has enjoyed three big meab-each day. The \ray examination since the operation above the entire stomach below the list phraem but still som what higher than is normal This I believe is due t an accessive dom as of the diaphragm since the operate the withdr the stomach from the heat on ity leaving space above ft

This case is rather unfouc in that although the entire stomach was thin the thora there as displacement of the heart in a y direction nor there y expiratory embarrasament as possible result of pressure. It was apparently ongenit I herrus, although the difficult labors in each on finement most not be overlooked as nosable tiological factor

In the surgical treatment of these conditions the route of operative procedure is of course a subject of great importance. The two cases found on record by Binnie as cured, were by the thoracle route. Heldenhein's case in Kienboeck a review as well as Balfour a case was by the abdominal route. There are certain factors in the thoracle route which make it more hazardous and a more difficult operation. It is a much more extensive operation requiring in many cases the resection of 3 or more ribs and in most cases intratracheal anaesthesia it is therefore a greater

I at 5 Roemtgemogram obbque view. The stomach is above the diaphram, the pylomes directed back. ed and down and mut anterior to the wane

shock to the patient. In the abdominal route the liver greatly obstru to the field but with untable retractors this can be over orme If the abdominal route is chosen I believe a sort of reverse Trendelenberg post ti n (Le head high and pelvis low) will be of advantage in making the field more accessible Whatever route a chosen the held i at best a difficult on because of the proximity of the vital structures and any new point in the technique or new method of procedure will be valuable

CARCINOMATOUS DECENERATION OF SIBACTORS (AND

By ISADORI SITE MID I AC be bl liller l Mirane 1 odus Ne

SAMULL BLKKOWITZ ALD. NEVA KK Surge on On P Date on I had a like of I

↑ LTHOU(H Stelwagon (t) and Ziegler (2) state that sebaceou cyst rarely undergo epitheliomatous degenera tion Ricker and Schwalb (s) in a monograph on tumors of the skin reviewing the whole literature to date report on as cases of epitheliomatou degeneration of schargon cysts The patient comprised and 16 females but mention of the wx of the remainder was not made. Ricker and Schwalb found that heredity played an unimportant role. None of the cases was congenital They could a certain no one exciting cause in one case trauma was men tioned as a predimoing cause while in another menopause

The ages of the patients varied one patient was less than 20 10 cases were 60 or more and 20 were in the fourth to the sixth decade

The tumors usually grew lowly Most of them were the size of a walnut some at tained the size of a man s jist

The predominant location of these tumors was the face. The tumor were located a tollows 8 had their origin in the mulbomian glands of the lids 6 were situated on the check 7 originated from the skin of the nose 3 from the kin of the forehead and upper lid 7 from the back part of the scalp I was situated in the skin at the inner angle of the eve I from the skin of the back I in the brea t 2 in the abdominal wall and 1 in the upper extremity

There is no mention of pontaneou dis

appearance of any tumor

In 17 cases out of 41 ulceration apparently played an important part in the transition to epitheliomatous degeneration

Bloodgood (4) in twenty years observed about 100 cases of cancer in accessible regions of the body such as the skin subcutaneous tissue and mucous membranes of the mouth tongue and hps The author feels that proper urgery in the precancilu accomple his 100 per cent, ure

In order to under tind the pith limit picture and clinical course of these growth a tudy of the embryology and hi tolegy schaceou cland i necessary

Hi tologically sebaceou gland or har tollicle gland are racemose or across gland in close relation to the hair follicles in the cornim (r) They con i t of a secretory por tion and a duct. The basement membrane of the gland i urrounded by dense connective ti-ue ari ing from the hair follicle or from the corum and contain the blood vesels nerves and lymphatics. Upon the basement membrane are several layer of epithelial cell - the outermost resembling that of the rete malpighi. In the layer the cell tre evandrical and columnar toward the inner portion they become larger and more or less cuboidal or polyhedral in hapi

According to MacCarthy (5) these gland originate from the stratum germinativum or germinating layer of the epidermi Down ward growth of these cells into the aboutance ou tisage a accompanied by differentiation into hair schaceous glands etc. Fich newly differentiated part retains a row of cell which corresponds to the embryonal tratum ger minativum

Pathologically the ordinary schaceou cyst is a retention cyst and arises from the occluion of the orifice of a sebaceou gland on the urface of the kin. There being no outlet the secretion of the gland continues to collect in the interior and form, a cy tie tumor. These are usually located on the face and scalp but may occur on any part of the body

In following the development of a sebaceous gland and the formation of a sebaceous cv t one can readily conceive by proliferation of the epithelial cells lining the cv t which correspond to the embryonal tratum ger

minativum it may undergo epitheliomatous degeneration. This proliferation may be due to irritation from within (as in Case 2) or as the result of ulceration of the cyst (Cases 1 and 3).

Within a period of twelve months we have had two very striking examples of the great value of early and complete removal of sebaccous cysts of the scalp that had under gone malignant degeneration. A third case seen by one of us (Seff) which terminated in general currenomators and death of the patient showed the result of incomplete removal of the tumor.

CASE J S mal age 5 years, admitted the Beth Jaruel Hospital, Normber 7 9 with thollowing history. At the age f ro he noticed small growth on the right side of the head. Included the did not increase in sure till be was 55 years of age after which it rapidly enlarged. The growth is came unfamment by continual uritation from combing his hair and finally opened with the discharge of seroastenineous full land foul smelling there.

Fig. Specimen \ 44.7 subcutaneous epithelioma succellulare. This specimen show the epithelial cell thin the ableou arranged in pseudopapillary form

material. The tumor was removed and be was told that it was schereous cyst. Within six years he had three recurrences of the tumor at the sit of the first operation, and was told each time that the growth was a schareous cyst. His blatory on it mission was a foll.

Nine months after the third removal of the growth 1 is fifteen months before the patient cam inder ou observation he noticed small growth in the same location, which gradually became larger and ulcerated. O evantination there is a growth about the size of butternit with crater like ulcerated preanance situated over the right the characteristics effected are not related and the characteristics effected are not related and its jurifice. The interformed potential surface is a surface in the property of the product to grow of the property o

Pathological report by Dr E. Moschcowitz specimen 357 (Fig.)

Four sections were taken from the tumor proper

Fig. 4. Specimen No. 4.1 epitheliom descript in 1 the periments sted the t (Case s)

the tumor with overlying skin from the ul erated edge of the tumor and from the subcutaneous tis ue beyond the margin of the growth

The tumor is a subcutaneous epithelioma con sisting of smaller and larger alveoli irregularly polygonal in shape with only a small amount of stroma intervening. The alveoli are filled with epithelium which is basilar at the periphery be coming more flattened and larger as we proceed to the central portion. The central portion of the alveolus is occupied by a necrotic finely granular material, shading gradually into the adjacent epithelium Within this necrosed material are hadows of epithelial cells some of which show faintly staining nuclei. These necrotic areas stain profusely with eosin. In some of these areas may be seen cross sections of the hair

The epithelium is irregular but regularly placed There are numerous mitoses and an appreciable number of epithelial pearls. In that portion of the growth situated beneath the cutis there is a distinct z ne of connective tissue intervening between the growth and the superficial epithelium infiltrated with abundant round cells

Diagno s Subcutaneous epithelioma with keratohyalin degeneration

One year after operation the patient returned with

a recurrence ituated just beyond the margins of the healed incision. The posterior cervical glands v. re. enlarged. The patient was impressed with the grave danger of allowing the growth to remain in the presence of the enlarged glands but would not submit to another operation. The patient ha since succumbed to general carcinomatosis

From an analysis of this case it is evident that malignancy is apt to occur in a imple sebaceous cyst as a result of inflammation and continual irritation Although the growth recurred four times the lymphatic glands did not become palpable until the last recurrence

CASE 2 Patient M M femal age 2 years came under our observation at th Beth Israel Hospital Dispensary November 2 1913 Six months previously (May 1913) he noticed a small irregular growth on the forchead which was slowly getting larger. This tumor was not painful or tender to touch but annoye i her from a cosmeti standpoint. Her personal and family history had no bearing on the present con lit on Examination revealed a small irregular swelling situated o e th

glabella about the size of an Imond which was attached to the akin t ne por t. The tumor was movable over the und rlying thanks It was somewhat irregular in outline but felt smooth \ submaxillary glands were pulpable. A pre-operative diagnosis was made of simpl scheceous yet Under local næsthesia (novocalne 5 per cent) the tumor was easily shelled out the ound losed and th patient advised to ret in periodically for observation. The tumor on cross at tion showed a granular mulberry lik tissu nelosing sebu cousmaterial i th center

CONCLUSIONS

I The origin of malignant changes in simple sebaceous cysts can readily be traced by a study of the embryology of the sebaceous glands

2 Malignant degeneration of sebaceous cysts may occur at any period of life.

Local irritation is an important exerting. factor in the malignant degeneration of a simple sebaccous cyst.

a Removal of all sebaceou cysts and more especially of those which are exposed to local irritation as on the scalp is strongly ndvised

5 Removal becomes urrent in all seba ceous cysts which are rapidly increasing in size even if the local glands are not enlarged

6. All excised sehaceous exists should be examined microscopically

7 Early and wide excision of the skin and ubcutaneou to us beyond the intiltrated or ulcerated edges of a school of a which has undercone malignant description offers a complete cure

FOLLICULAR ODONTOMATA OF THE SUPERIOR MAXILLA

A CONSIDERATION OF INTRANASAL DRAINAGE FOLLOWING ORAL REMOVAL

R CARL W MAIDRON MR DDS T * T CAM

THE question of the relative ment. of oral or of nasal drainage in the surgical treatment of suppurative disease of the maxillary sinus has been one of long standing difference of opinion. In a personal observation of more than 50 cases occurring in the service of Dr S J Crowe at the Johns Hopkins Hospital both at opera tion and during the post-operative course the great advantages of intranasal drainage were apparent When chronic maxillary sinusitis is unaccompanied by disease of the frontal or ethmoidal sinuses the modified Caldwell Luc operation is followed by rapid recovery and cessation of discharge. Thus the long-drawn-out post-operative course of oral drainage is avoided. The frequent painful dressings the dread of which is considerable - and the insertion of gutta percha plugs etc are unnecessary. If of dental origin the offending peri apical area as well as the pulp chamber and canals must be treated urgically or the tooth extracted In no cases was there evidence of ill effects upon the nasal mucosa following this treatment aside from temporary swelling lasting but a few days

The excellent results following this method of treatment suggested that follicular odon tomata involving the maxillary inus might be also treated in a like manner. Here there i no question of post-operative infection of the nasal mucosa recovery is usually prompt and post-operative treatments are not painful

Dean has reported a case of compound follicular edontoma drained through the antrum into the nose and the external opening closed Aside from this instance, the treatment generally adopted is that of oral drainage

PECHNIQUE

The technique varies with the individual case but usually follows that of the Caldwell Luc operation A horizontal incision is made through the alveolar mucous membrane well up toward the reflection of the mucous membrane and extending from the anterior to the posterior border of the tumor Care is taken to preserve the mucous membrane intact and uninjured making vertical in cisions if necessary The cyst walls are completely removed from the surrounding bone The maxillary sinus may then be incised if it has not already been opened in the dissection A large opening is then made from the cavity into the inferior meatus of the nose anteriorly Through this opening a curved clamp may be passed from the antenor nares into the cavity to grasp an iodoform gauze cigarette drain which is in

Ing Root cyst involving the left maniflury sinus.

serted through the oral incision. The gauze which extends some two inches past the protective covering may be moistened with hydrogen perconde and lubricated with sterile vaseline. It is lightly peacked against the walls of the cavity maintaining in place any mucous membrane flaps which may have been preserved. The oral incision is closed with interrupted fine catgut sutures. The drain should be removed from the nose in 42 to 48 hours. This may be followed by slight bleeding. A few post operative mass! Irrigations may be advisable.

This method of closure has been most successful the incisons healing per primam. In none of the cases of maxillary sinusitis did the wound re-open as is reported by Dean, who for this reason has substituted slik worm gut satures tied over rubber tubing. The excellent union is no doubt due to the fact that the incusion is made at the reflection of the mucous membrane, which is at a considerably higher level than that described in textbooks. At this level the submucous tissue is greater in amount and therefore more easily approximated. In one fustance

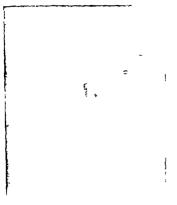

following the removal of an extensive odon toma the anterior end of the oral incision reopened communicating with the floor of the nose (Case 3). Attempt will be made to close this at a later date.

CASE REPORTS

CAN R N female gs 36 complained of a swelling of one year durnlow beneath the left eye. The enlargeme t had been gradual and uncompanied by pain. There was in history of chroni nasal discharge and the nasal examinati in was egative. I addition to the tumor which was firm and crepitant and situated above the cuspid bloucydal and first modar teeth on the upper left sade examination of the mouth aboved the absence of the pre-left first bicuspid. The patient did in t know whether it had erupted and had been extracted or not. The onligeogram (Fig. 1) did not reveal the misling tooth nor was it found at operation thet no being not-cyst. DEPARTMENT OF TECHNIQUE

AN OPERATION FOR THE CORRECTION OF DEFORMITY FOLLOWING

B JOSEPH F SMITH MD R u V

HOPART'S amputation of the foot is open to the well hown objection that it removes the front of the foot in such a man ner that the weight bearing bone the astragalus is deprived of the support normally afforded it by the front of the foot and tends to be pushed forward against the cicativit, producing painful tension and pressure. Besides, the tendo Achilles unbalanced by the action of the does flevors, raises the heel thus rotating the astragalus for ward and tending to protrude the latter bone still more against the cactrix. The elevation of the feel by the unopposed action of the tendo Achilles may even produce such marked back

ward tilting of the stump that the cleatric becomes part of the weight bearing surface, thus adding still more disconflort n any attempt to walk or bear weight upon the stump. Division of the tendo Achilles gives only temporary relief and the procedure of implanting the dorst flevor t nd ns into the plantar flap does not always suffice to overcome the difficult because in this implantation it is difficult to secure the necessary leverage to give the tendons action

I spate of the objections to Chopart samputation, it is still described in all the textbooks and is apparently the operation employed rather frequently in railway surg ry

THE TREATMENT OF FRACTURES BY VAIL EXTENSION

A PRILLIMINARY RUPORT

B PRIDIRICA G DIAS MD CERCO

This purpose of this paper is to make a preliminary report upon a series of cases treated by the nail extension known as Steinmann's method. The rapid development of the treatment of fractures and the bewildering rapidity with which new methods have been proposed within the past few years prove that the treatment of fractures is still in the developmental stage, and also demonstrates a renewed interest in this subject which roentgenology has brought about. If one may take Hoffa's statement as correct that two-thirds of all invalidism is lue to fractures, it is only string that a subject of such great economic importance should receive a proportionate share of attention.

Possibly the greatest interest in the operative treatment of unreduced fractures was attinuated by Lane. He leads that school which believes in an immediate complete automic resiliution by open operation. The opposite school is led by Lucus Championniere who believes that first ion of the fragments is not the first consideration but preservation of function this to be obtained by immediate mobilization and massage. As Steinmann has pointed out each of these extremes is probably wrong the ideal method being one which would include the good features of the early anatomic restitution and also mobilization of neighboring joints.

It is unnecessary to enumerate the yest num ber of methods used in the closed treatment of fractures. This subject may be dismissed with the observation that in many cases these old time honored methods suffice to bring about good functional and anatomic results. The open operation which has literally been done to death in the last five years especially in the hands of those who are not equipped either by training or environment to properly execute the technique involved in a precedure in which the element of infection is so great a hazard, requires only the statement which I believe will receive the support of every experienced surgeon that open operation must necessarily carry with it the danger of infection. Infection is frequently disastrous to the limb and often to the life of the Therefore, open operation must be strictly reserved for that class of cases which is not amenable to other methods of treatment

As Anschuetz observed the nail e tension of Steinmann is to be regarded in the light of a compromise measure between the frequently nefficient closed method and the hazardous open operation. The nail extension method is not original with Steinmann who got hi iden from the Malpangue hook so familiar in the pages of textbooks on unger. Thi apparatus resembled nothing to much as a pair of ice tongs. Helisecke later in ented an instrument which was quite smillar in the blades, handles, and direction of pull to an obsterite forceps.

Codix lla in 903 used an extension by mean of pla ter f Paris which an world well in man cases, but the tendency of the pla ter of Fari-

wa to produce a pressure necro-i-

From these methods Steinmann developed in procedure which he described as a method of extension which exerts a continuous traction exclusively by the aid of nais or steres which are driven either in or through the bone whenever possible through the lower fragment. The original method was to drive a nail transvenely, through the lower fragment. This later was modified and two nails were used, one on each side being portfully driven through.

The method of the mirroduction of the nail has been modified at virious times. First the hole was drilled through the hone and the nail introduced through thus drill hole. Another method was by preparing a nail with a square head which could be received into a brace and bored through the acarpenter might with a brace and blt. This method is probably the best. However it is quite possible to introduce the nail in the first manner by simply dri nng it through with the hammer.

Various types of nails have been used both by Steinmann and other operators, but experience has aboven that the simple round nail with the sharp point answers every purpose. A special extension apparatus to be applied to the nail it self was devised by Steinmann, but the copper wire loop is quute as useful.

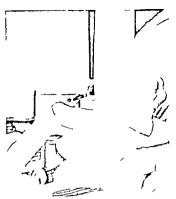

The point of introduction of the nail is of great importance. It is a cardinal principle in the treatment of fractures to postpone operative procedures until the inflammatory reaction or hermatoma has at least pertially subsided. Thus

Fig. She min path to be dwith the tit hotonial through $p_{\rm tot}$ all

holds true equally well tir the nail extentin because the introduction of the nail necessarily converts a simple int a compound type of fracture and add a torcign body Therefore in electing the point for the introduction of the nail avoid if possible area in which the soft parts have been traumatized and endeaver to utilize a portion of the hone which will not in vade the medullary cavity. A ituation clive to the epiphyseal line 1 ideal except in the case of children and young adult in which epirhy eal ossification is incomplete. Furthermore it is de strable to avoid injury to the joint capsule which can usually be done by a consideration f the anatomy of the parts before introducing the nail

The technique of the procedure is as follows The skin is disinfected in the usual way tenctoms incision is made down to the bone Usually it is possible to select a site in which the bone is almost subcutaneous. The edges of the small incision are held apart by untable retractors the nail grasped in a heavy forceps is introduced through the tenotomy inci ion until it comes in contact with the resisting bone. point of the nail is then given a suitable direction and forced through either by the hammer the hand drill or an electric motor. It is a good plan to have an as.1 tant make pres ure upon the opposite side of the bone with a wooden block covered by terile linen to receive the shock of the hammer blows or the drill force. When the skin is seen to be elevated upon the opposite side a second mall incision is made and the nail forced through further until an equal part protrudes upon each side of the bone. A collidion dressing is then put upon each wound. This is c vered by terile drestings a sterile c pper vire loop attached and finally the held in place by a terile roller bandage

F h path tin bedand ight ppled firm tur of ppe part of

In our work thi procedure ha alway been carried out under general anæsthesia. However steinmann. Anschuetz and other report succes with local anaesthesia it being claimed that the only pain ari es from the soft parts and perioderium.

Traction is then applied to the wire loop by means of a rope which is run through a pulley and a suitable weight attached the amount of traction being controlled by frequent X-ray pictures. The direction of the traction can always be modified in such a manner as to exert the pull in a line continuous with the long axis of the fragment involved.

It is unnecessary to take up in detail the various ituations in which a nail may be introduced. Suffice it to say that it can be used both in the upper and lower extremities. However its chief field for use is in the lower extremity be cause of the necessity of overcoming the short ening councident upon the contraction of the heavy muscles of the thigh and leg.

The nail may also be u ed as a lever. This may be accomplished in one of two ways. For instance, in outward rotation of the lower extremity in fractures of the neck of the femur in which uitable invarid rotation cannot be obtained. A nail driven into the great trochanter of the femur in a line parallell the long axis, the

Fig. 3. Roentgenograms of Case before and after application of nail extension for fracture of the right tibia and fibula.

neck of the femur and attached to a rope and weight running through a pulley will tend to bring about and maintain overcorrection of the outward rotation.

Another method of using the nail as a lever is by hanging a weight on one or the other end of the pentruding nail thereby bringing about rotation in the direction desired. The duration of the traction is governed by the amount of correction of the pre-existing deformity. The optimum time is eighteen to twenty-one days. During that period a certain degree of pressure necrosis takes place and this is usually more than enough turne for the correction of the overriding of the fragments if sufficient weight has been applied. The pressure necrosis makes the removal of the nail easy because of the increased caliber of the The mail may remain in silu bowever nell bole for a considerably longer period of time depending upon the judgment of the surgeon However the danger of infection necessarily increases with the duration of time. One case was reported in which because of the intensity of the traction the nail cut through the os calcus, in which it had been introduced too near the plantar surface exactly as a dull knife would cut through butter The nail was removed, no infection took place and healing occurred without complications.

The intensity of the traction is determined by the progress with which the deformity is overcome. Ordinarily the disconfort resulting from any traction necessary to overcome the deformity is not great and speedily diminishes.

Lateral dislocation of the fragments may be treated with the extension in place by means of

Fig 4. Roentgenograms of Case showing position of fragments before pipheation of nail extension and after

a loop of adheave passed around the offending fragment and attached to a weight and pulley Dislocation of the fragments in the loogitudinal direction with complete separation of the fractured ends is possible because of the great traction exerted and must be carefully watched by the roenigen control

It is perfectly possible with the nail extension to keep up functional treatment. This is a creat point in favor of this method. Another advantage is in the treatment of compound fractures because of the fact that the nail introduced frequently at a point rather remote from the place of fracture it is possible to begin the treat ment before the infection has subsided thus gaining much time. Furthermore it gives per fect access to the wound and thereby permits of frequent dressings. It is especially indicated in those types of fracture which are n t recent and which are complicated by considerable overriding The longest time at which the method has been used for this class of cases is in one reported by Anschuetz, in which the nail extension was anphed to an ununited fracture 142 days after the accident, and a good functional and anatomic result was secured. In alcoholics and demented individuals it has also the advantage over many methods that it cannot be removed by the naticat.

Among its disadvantages may be mentioned first the danger of infection. However as the nall is frequently introduced through the oscales, a bone which has no medullary cavity and

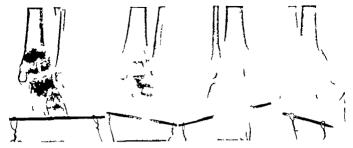

Fig. 5. Roentgenograms of C. se 3 showing frait re of both leg bet re. d. it rail cation of null. tension

which because of that fact is hard to infect the danger from that source in fractures of the leg is veri slight. It is true that the danger increases with the introduction of the nail in the long hollow bones, but if the precautions outlined by Steinmann are borne in mind this is relatively light.

A second objection is the apparent brutality of the method. This is altogether theoretical and not real. Our experiences with a number of cases so far have demonstrated the fact that there is no more discomfort with the nail extension than with the Buck's extension in many cases not as much. It is true that fatablities have resulted from this method as from any other population of fracture treatment, but the proportion of infections resulting from the nail extension as compared to the radical open operation we be live is yer, small

Injunes to the soft parts may result from the introduction of the nail. In Case a of our series a nail perforated the posterior tibial artery incision was merely enlarged the vessel picked up and ligated and no unfavorable results oc curred. This has occurred in a few reported cases but in no instance was any permanent lamage caused Decubitus in the region of the nail hole has been reported but did not occur in any of our cases. Because of the intensity of the traction exerted it is possible to cause an ivercorrection that i a separation of the frag ments in a longitudinal direction. This may be controlled by frequent \ ray examinations and is easily reduced by lessening the amount of traction. The enormous traction also may be utilized for the lengthening of the soft parts where contraction has resulted from improper reduction and immobilization at the time of the injury. This is a great help in the treatment of old fractures.

Lateral dislocation is frequently overcome simply by the traction in the direction of the long axi of the limb the tendency being for displaced fragments to fall into position when the intensity of the traction is sufficient to overcome the over riding

It has been argued by some that the method Jelvis union because if the tendency to separate the fragments. This is a purely theoretical objection because the traction is released a, soon as the difformity is overcome and a permanent fixation dressing such as a plaster cast i immediately adjusted. We have not observed thi in our cases.

Among the advantages of the method may be mentioned hist that from a mechanical stand point no other procedure can be expected to produce as strong fraction. It is not more painful to the patient than less efficient methods. The traction is exerted directly upon one frigment and not merely upon the soft parts. The traction exerted by the familiar Buck's extension is exactly comparable to making traction upon the arm by pulling upon the coat sleeve. There is no direct pull upon the fragment.

In those fractures of long bones in which one frigment is very small as in fractures of both bones of the leg near the ankle it is of great ad vantage to apply fraction in such a manner that ankla a small area is needed for the attachment of the traction apparatus. No plan has yet been devised which requires so little space for its

attachment as does the nail extension of Stein mann. This is of further importance from the fact that it permits free access to open wounds in compound fractures.

I wish to refer to a few case histories of patients treated in Look County Hospital by this method.

"CAR. The patient made suffered fract to of the tright tible and fidula boat hand breath hove the lower artendar surface of the tibes, also fractions of the internal made load. The fractions of the tibe and there was no exciting of the fragments of about an anch and half. Repeated tempts i reduce to other mentions of the fragments of about an following the fragments of the fragtions methods failed it reduce the fragments.

December 5 of under either nestthesia and most carried asspals small temotomy locision is made over the os each on its in ode. With post wire nail of locks long, as a direct through the bose transversely applied, to the lock of the locks applied out exert jud on the locker fragment of the thus, bringing in thos alignment with the opper fragment. The nail protrated about 1 inches on each side of the record, The wound was sealed with obligation of steriled could be seen to be supported to the seal and extremely made by resume of a rope and pulley tracked it this copper in which of the properties of the seal and extremely made by resume of a rope and pulley tracked it this copper in the

CONTINUAL STOMACH LAVAGE AND CONTINUOUS HYPODERMO-CLISIS IN PERITONITIS PERSISTENT VONITING WITH DEHYDRATION AND DILATED STOMACH

WITH A DESCRIPTION OF A MODIFIED MONACH TUBE

BY ALLEN B KANAVEL M.D. CHI 466

THE separate or combined use of continual t mach lavage and continuous hypo dermocly 1 in the dehydration and toxe mia incident to peritonitis has proved itself of uch ignal benefit that it would seem to be worthy of wider appreciation. It has also been used with great satilitaction in persistent vomit ing of any type in dilated stomach atter opera tion, and in imilar tate, while the continuous hypodermoclysis in addition to being used in combination with the gastric lavage may be used in dehydration and toxerma from any cause To make the procedure available certain changein the ordinary technique have been devised

TOMACH LAVAGE

For urgical purposes a stomach tube modified from the Einhorn and Rehtuss types has been devised. This modification is necessary ince we wish a tube that can be inserted in the stomach and lett in position days it necessary moreover the tube hould be one that can be introduced without the active co-operation of the patient ince it hould be available even though the patient be nauseated and vomiting continually or be till anæsthetized The tube and it, carrier are constructed a

follows. The bulb 1 of the same 1ze as the Rehfuss bulb except that the lumen of exit i larger and it is so con tructed that it is impossible for the wire carrier to slip out. The rubber tubing is of the same ize as the Rehtu, s tube but only 30 inches long being attached to a second h avier tube inches long by a screw lock rarrier of piano wire i made to fit the first tube so that it can be introduced without difficulty The second tube is attached after the removal of the carrier and the contents of the stomach a pirated or siphoned off

It the patient will swallow the tube the lumen

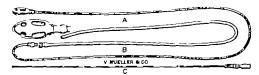

Fig. Stomach lavage tube, bulb pd was carrier

of exit of the bulb being larger than the Retifusa tube the stomach contents can be asplirated with greater freedom and the mucus interferes less. This latter is of considerable importance in post-operative lavage when the mucus is generally considerable and interferes even with this tube at times. It will be seen that the bulb is so constructed that the point of the wire carrier cannot slip out of the bulb and injure the stomach. Owing to the abortening of the rubber tube time, there is less probability of the collapse of the tube upon suction and there is less difficulty in removing the carrier. This latter procedure is also aided by having the patient throw his bead back thus lessening the sharp angle in the tube

The tube described has proved of signal benefit in the vomiting of peritonitis or persistent vomit ing from any cause as well as being of great aid in the routine examination of stomach contents for diagnosis. In the former instance the tube is either introduced by the surgeon, or is swallowed by the patient. It is then attached to the chin by a piece of adhesive plaster and may be left in for days. In the regurgitation incident to peritonitis, the stomach contents are aspirated every half hour to an hour and at regular intervals the atomach is washed out by injecting soda solution, or other liquid, through the tube and aspirating it. Between the washings the end of the rubber tube attached is placed in a basin with the end covered by fluid so that a continuous alphonage takes place. The retention of the tube is a ithout discomfort, a hile the absence of stomach distention and comiting gives the greatest relief to those distremed patients.

Fluid may be left in the atomach or medication given if desired. In one patient with personalist who was apparently morbinal the tube was kept in the storach four days and the patient did not vomit after the treatment was begun although he had been reguigitating large amounts previously. In addition to being used in perticular, and the substantial properties are the substantial properties.

ing from any cause, as paralytic ileus, gastrilis, tourmic vomiting etc. In such patients after washing the stomach for a day or two small amounts of liquid food are introduced and if subsequent suction shows that the food is being absorbed or is passing the pylorus, feeding is increased. Thus without discomfort to the patient we give food at the earliest possible moment.

If the tube passes the pylonis, as it may do upon the resumption of the normal stomach peritalist, the duodenal contents are then aspirated which may be of benefit in some cases. It has occurred to me that it night be possible to carry the tube through a gastro-enterostom opening at the time of operation and thus aspirate intestinal contents or introduce food. I have not attempted this, however.

CONTINUOUS HYPODERMOCLYSIS

In patients suffering from dehydration from any cause or from toxemia, the administration of large amounts of normal saline during several days has long been recognized as of great value The administration of this at stated intervals, calling for the reinsertion of the hypodermoclyms needles, thus distressing the patient and entailing much work on the part of the surgeon has militated against its more common use. To obviate this the following technique has been satisfactory The ordinary hypodermocivals set has been used with the e-ception that the peedles are much finer than are those commonly attached and provision made so that the solution can be shut off from either needle. The needle chosen is four inches in length, No. 20 The assistants are impressed with the fact that no pain must be given the patient either during the insertion of the needles or the administration of the solution. To obviate this the akin is blistered with a few drops of novocaine (1/2 per cent solution) using the finest hypodermic needle then a few drops of the same solution is forced along the course we expect the

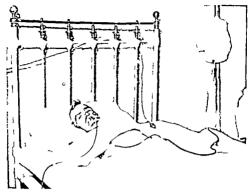

Fig a Showing polic to fapparatus

needle to follow in the deeper tissue. The point of a fine sharp hypodermodyns needle is then placed against the skin and gently rotated with irm pressure. This carries the needle in absolutely without pain. After being in place the head is wrapped in gauze so that the flange does not touch the skin and cause pressure and the needle is fixed in position with adhesive plaster. The solution is kept warm by frequently refilling the can or using a sterile hot water bottle in the can. The solution is allowed to drop in slowly never distending the tissue to the point of pain. Whenever the patient says there is a sense of fullness the rubber tube on that side is shut off

In this manner we have frequently given continuous normal salt solution for three to four days with no discomfiture or ill consequences to the patient. We have used it in children with out the slightest complaint on their part. Its use has become a routine in all cases of persistent vomiting and toxemia as pentonius ileus per nicious vomiting of pregnancy toxic nephritus septicemia etc. In debilitated patients we have inserted the needles and begun hypodermoclysis at the beginning of an operation and returned the patient to bed with the needles in place and continued the administration indefinitely have used it supplementary to rectal administration of tap water and in those cases where owing to the nature of the operation e.g. intestinal As an example resection this could not be used I amination of the charts shows that in a seven year old child Wesley Memorial Hospital No 56 931 suffering from paralytic ileus 4000 ccm were given over three days, and in a patient with general peritonitis, Wesley Memorial Hospital No 57 188 following appendicates in a young man 0000 ccm, were given over four days. And in another patient, Wesley Memorial Hospital No 50 154, much dehydrated from persistent vomiting 13000 ccm were given in 44 hours.

In cases where the heart is growing weak there has been at times a tendence to water logging of the tissue. Therefore such cases are watched carefully so that on the one hand this will not occur and on the other we shall not overload the circulation and strain the heart.

The benefit patients suffering from peritoritis have deny-d from the combined use of continual gastric lavage and continuous hypodermoclysis is far beyond that secured by any other procedure with which we have had experience.

THE USE OF ELECTRIC LIGHT AND HYPOCHLOROUS ACID IN THE TREATMENT OF WOUNDS

B (LORGE W CRILE MD) FACS (14 Ort

OR some years the electric light has been utflixed in the treatment of burns and in the literature we find occasional mention of the efficiency of electric light treatment for obstinate ulcerating surfaces, such as varicose ulcers, etc. Apparently however the wide applicability of this treatment has not been recognized if one may judge by the paucity of the literature under this heading. Chaput, writing in 1014 states that the wide usefulness of electric light baths was discovered by him during a dark season in which sun boths were unavailable In many kinds of cases he therefore tried the effect of exposure to the light of a fifteen-candlepower electric lamp applied daily or every other day for bourly periods. As a result of these trials, he found that in the ordinary electric lamp we possess a simple, practical economical, and very efficient means for treating obstinate ulcers, and infected and gangrenous sores. Chaput pre dicted also that this concention would find its application in the treatment of certain complications of the wounds of war

Last year at the American Ambulance in Paris, Dr. Winchester Dubouchet called my attention to the value of electric light in the treatment of infected wounds. D. Dubouchet used ordinary electric lamps, ungle or in clusters with r with out reflectors, the treatment in each case being continued inght and day. We gave the method a frail on my service and secured so much bette result than by the use of dreasings that upon the return of the Lakeside Unit from France with introduced this treatment in Lakeside Hospital and Inserved its effect upon various types of wounds.

What the voeriences of war had proved to military urgeous soon became of your t us e. that little if any advance in the treatment of infections had been made in many years. We soon realized also that the real reason for the efficiency of the electric light treatment lay in the fact that Nature own method of promoting repair is thus produced artificially as is demonstrated not only by Chaput's successful substitution of electric light for sun baths, but far more strikingly by the remarkable facility with which wounds head a desert places. For example in Arizona, where the air is dry and rare and the rays of the sun are direct and strong the carenof an animal does not readily decompose. In thi region, tuberculosis is easily cured and tuber cular legions of the skin and superficial parts heal ranidly

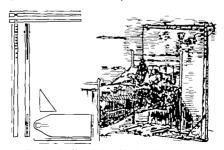

Fig. The Fuller adjustable bracket for applying electric light treatment to outsits.

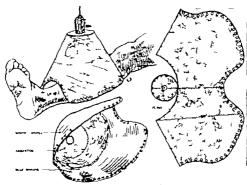

Fig. The Bill metal bood firelectric limi

Analysis of sunlight and of ordinary electric light show that they are practically identical. If view of these facts, although we have recognized the therapeutic value of the Finsen ray the Coolidge tube etc. we have been slow to appreciate that by simply utilizing the rediance and warmth of the ordinary electric lamp we may bring the dryness, the heat, and the light rays of the desert to the wound to promote its healing.

The omissions of dressings in itself is an important factor in the success of this method for Berkelev Moynlhan has stated that the average dressing of a suppurating wound is in effect a pus poultice. Indeed until I observed the behavior of wounds exposed to the air it had not occurred to me that in dressed wounds the preater part of the discharge was due to the irritation of the dressing

It is not my purpose here to discuss the theories which may explain the value of heliothermy or electric light thermotherapy. These are sufficiently presented in current journals especially those devoted to electrotherapy and radiology. Nor shall I present the chemical formule and reactions which indicate the reasons tor the efficiency of hypochlorous acid as an anti-spitic eleanning agent. These are fully discussed in articles by Dakin and Carrel. My purpose in this jusper is to describe the manner in which we are applying electric light treatment and hypochlorous acid in a variety of cases. An apparatus devised by Miss Fuller and Dr. Bell

of the Lakeaide Hospital (Figs. 1 and 2). In which electric lamps placed in pasteboard con or in metal hoods are suspended from an adjustable frame has proved a practical and comfortal means for applying light treatment to wound the neck chest shoulder arms or legs. Fabdomial wounds, the lights may be suspended from a cradle. The amount of light and the proximity of the lamps to the wounds are go erned by the comfort of the patient. For it necessary cleansing of the wounds we use Dakir solution. You will be solution.

Osteomydit. In cases of osteomyditis temporary pack is placed over the wound umm diately after operation to prevent oozing. Aft a few hours this is removed and the undress wound is exposed to several electric light bul suspended under a cradle (Fig. 3). The bul are near enough to the wound to subject it to comfortable warmth. Secretions from the woul are cleansed with Dakin's solution and it coag lated scrim develops, a hot pack with Wighhypertonic solution applied for half an hour more cleans up the held. In some cases it exposure to the electric light is continued bo

night and day. Aside from the box pack and Dakin's solution no other dressing or antisepte is employed. Our experience with the electric light treatment in osteomyellish has demonstrated three outstanding advantages the wounds heal more rapidly, much less dead bone appears the wound discharge is markedly decreased.

Open granulating nounds. That akin grafts do better without dressings is well known, but under exposure to electric light not only cases requiring akin graft but all open granulating surface wounds show notreased heding power.

Open tubervalous absenses. We find that during the first alght it is best to pack a tuber culous abscess in order to establish an open hypochlorous acid cleaning the \n ray being used also while the wound is wide open. We have found that many of these wounds may be atturred within five days, and that fairly good primary healing follows.

Dry drainage. In cases requiring gall-bladder appendiceal, or pelvic drainage, we find that they progress well under intermittent exposure to electric light and that the patient is much more comfortable under the heat and light.

Cancer of the month. After the excusion or cauterization of cancer of the mouth, hypo-

chlorous acid is especially useful because it is a deodorant, and not an irritant or a posson.

Empyema The malodorous properties of empyemata are plendidly controlled by the injection of hypochlorous acid

toute nifect as In the treatment of acute infections of the joint and of the deeper soft parts the combination of a continuous irrigation with Dakin's solution through multiple drainage tubes, with exposure to a Custer of electric lighty produces excellent results. In every acute cases the drip irrigation should continue by might as well as by day. Wright's solution also is efficient in these cases.

Aseptic closed wound. We have made a number of observations of the effect of exposure t electric light on swept or closed wounds and have found that the patient was much more comfort able than with dressing, and that the wound benting was at least as rapid.

CONCLUSION

All living tissue attempts to encyst or to cast off foreign bodies of all klods. No one would consider the adrisability of putting a gause dressing on a corneal ulcer and yet the violent reaction of the eve to a foreign body differs in degree only-not in kind-from the reaction of living thrue t dresungs anywhere. We know that we dare not puck gauge on suture lines not We know that nails and acrews drain fractures cause the absorption of bone that any aseptic wound with drainage discharges much fluid that wounds roughly handled during operations discharge more fluid than clean cut wounds. We know how difficult it is to bury steel plates in bones to bury heavy silk in aseptic wounds From the benefits of dressings must be subtracted all the resultant ills-irritation and discharge added necrosis, pain, and discomfort. Frequently changed hot dressings are more comfortable than plain dressings and perhaps produce less pus but if applied too long they tend to waterlog the tissue. Moreover the wet hot pack gives no different quality of heat than does the electric light, and the beat from the electric hight penetrates outte as readily as the heat from the hot pack

Wounds heaf best when infection is hindered or destroyed by the agent least harmful to the tissue and without the irritation of foreign bodies in the form of dreasings. All these entare served by the use of hypochhorous acid solution and by exposing the undressed wound to constant light and warmth.

THE APPLICATION OF THE SEWING MACHINE STITCH IN CASTRIC

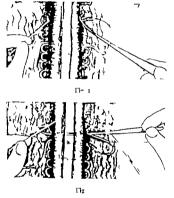

BY E. P. OUAIN M.D. FAUN BISMARCK N. RTH. DAK TA

THE illu tration pre-ented herewith demon trate a needle devised by the writer for the purpose of applying a double inter-locking suture in gastro-enterostomies and enter-neutrostomies. The needle is threaded as shown in Fig. 1 and the other end of the catigut is 11 tened to a blunt traight needle. The needle is pushed far enough through the two structures about to be utured seroea to-seroea fa hion so that the eve near the point clear the distall.

mucosa by about one tourth inch. The trught needle with the other end of the latest 1. In we put through the catgut loop near the muss a. In Fig. The first needle 1 withdrawn and the titch pulled light.

A DETACHABLE APPLIANCE FOR THE CONVERSION OF THE OPERAT ING CYSTOSCOPE INTO A DOUBLE-CATHETERIZING INSTRUMENT

By P. S. PELOUZE, M.D. PHILADELPHIA Cystemopet Urriogoni Department Jefferen Medzal College Hospital

W. HEN one tifes to pass two uneteral catheren through the Buerger operating cystoscope which is the one most generally used in this country be finds that they stick to each other kink in the channel, and do various other things to promote failure. After a few such experiences, be realizes that the instrument was surely not intended for double catheteriax tions, and is compelled to resort to the instrument especially designed for such work. A study of these two instruments will show that, as far as the outer sheaths are concerned, there is really no essential difference and as regards the penscopes, the only important difference is that that of the double extheterizing instrument

for which it was made, but it increases the range of intravesical procedures at one passage of the instrument, a point very gratifying to most patients

One field in which I have found it of particular value is that of separate renal function tests. During such a test the study of the separate unnes is of greatest value and it is usually a simple matter to collect them. A number of disappointments in separate efficiency tests has shown me the fullity of looking for accuracy in such tests by inserting No 5 or 6 F catheters into both ureters. The leakage into the bladder during the test period is generally so great as to render the residings uncleas, as it is imposed.

Operating cystoscope with detachable fin by which instrume t ca be connected with double eathererising cystoscope

has a fi ed fin to divide the unoccupied lumen of the sheath into two separate catheter channels.

Usually the double catheterang scope is purchased first, the necessity for operating arises, and the physican learns that he must buy an entire new instrument. The similarity in the outer sheaths makes a part of the investment appear unwarranted, but each periscope fits its own particular sheath and there are no universal fits.

To overcome some of these difficulties, I have devised a detachable separating in which makes it possible to convert in a moment a time, the operating cystoscope into a double cathetening one that works equally as well as the one made for that purpose. This little appliance is so well illustrated in the accompanying cut that it needs no description.

Not only does it admirably fulfill the purpose

while to state positively from which kidney it came. On the other hand, if one collects his urines for study withdraws the catheters, removes the fin, and finests the tapering Garceau catheter into one ureter until it entirely fills its lumen and collects the other kidney a trine from the bladder there practically ceases to be a margin of error to consider.

The addition of this appliance to the operating systescope in short, gives one all of the range of mediulness of two models and at a cost very little above the price of a single instrument. While this may not make a strong appeal to the manufacturers, it makes an eloquent one to the physical who starts out to buy an outifi for cystoscopic work. As previously stated, there are no universal tits with these instruments, which

fact, unfortunately makes it necessary to fit the attachment to each individual cystoscope.

CONTINUAL STOMACH LAVAGE AND CONTINU
OUS HYPODERMOCINSIS IN PERMIONIMI
DEHYDRATION FROM VOMITING AND AL
LIED CONDITIONS

Dr. Allen B Kanavel presented a paper en titled Continuous Stomach Lavage and Continuous Hypodermolysis in Peritoritis Deby dratt in from Vomiting and Allied Conditions (See p. 43)

DISCUSSION

Dr. DANIEL \ EISENDRATH Dr Kanavel has presented an excellent idea because there is one factor in acute gastric dilatation (post-operative) that we are apt to overlook and which this tube will help greatly in removing. Everyone has probably noticed in cases of acute dilatation that after you have washed out the stomach and have not given the patient a drop of water by mouth, inside of three or four hours there will be an accumulation of more or less fluid again. It took me quite a while to under stand that this is due to hypersecretion from the gastric mucosa. There is very little or nothing said about this condition in the literature It is a sort of gastrosuccorrhoea. It seems to me a tube which is kept constantly in the stomach will help greatly because, after the preliminary washing out a suc tion tube will take care of the disagreeable hyper secretion

There is one thing in this connection I would like to call attention to which we have observed recently and have their to control as much as possible, and that is determination of the amount of carbon dioxide. Dr Wright is working out the relation between acidosis and gastric dilatation Many of these cases are instances of acidosis and the

moment wan introl that havegrated a ren our intribute havega in foliatation

THE UT OF NAIL ENTEN IN IN FRACTURED BY I CONTROL OF A CO

DICL DIX

DR KELLER SPEED I would like to as a 1 word on the method because I has been using tor two varianth chall associated

First tall the opper with spinal people, history and I may a will tell it to out. In the first ase in when he was all tell it to out. In the first ase in when he was the loop and put it on the naise the was in table to get a wire loop and put it on the naise the was in table to get it ture wire with he has defined by the worked of well that we adopt it it is subsequent uses. For the nail I have been using steed drill rod a we sust not an inch in diameter at off at the required length. The traction on the nail and be relieved it the patients of tressed be moving it and replacing it. The nail also control the amount of rotation to either iden in fractures of the femur when applied to the femur itself. The nail becomes loose in the os cales in about 150 or o day.

We have had two cases of accident in connection with the nail in the hole. In one in the that week the patient getting tirted of the traction realised down and pulled the nail out but the interne dictorered this quickly and by injecting a mall amount of fodine in the hole through the bone we avoided any infection.

The second case was brought to the operating room for the removal of a nail as it had become loose In fractures of the femur of which I have had but few cases, I have found the nail is not loose in three weeks. I use a much larger nail through the femur in such cases.

I have had one case with a result after three weeks by traction from the femur seemingly as good as that shown. The leg was put in a cast after that time and the fragments slipped back because the callus was not hard enough. In subsequent cases we found the results were better when treated for five weeks with a noil through the femu. In the pictures Dr Dyras has aftern us in one case I am sure that the nall was not put through the os calcia. That does not make any difference, because if the nail is pulled very hard it may pull through the os calcia and impings on the heavy plants fascia and plants through will bold just as well as book will. This method has been tried by posturing a nail or through the bose it sell, but in the space in the tendo Achilles and I he more in the or calcia and it works to use a well.

The apparatus Dr. Dyras has shown you for foot drop it seems t me, is entirely unnecessary because when the extension is applied to the on calcil there is absolutely no tendency for the anterior portion of the foot to drop down. At least, I have never seen it. The or calcil itself, on account of its cancellous structure, laterates under this type of treatment, and the null is easily inserted.

I want to say a word about the intensity of the traction in the knee and ankin. The separation that was pparent in some of these cases is due to the stretching of the joint ligaments. That is not of a permanent character because after the traction is relieved the joint resumes its normal condition and there is no permanent damage done of which I know

The results are not distinctly anatomical. I have never obtained a satisfactory X-ray picture of a case that showed anatomical reduction, but functionally the legs are brought into weight-bearing line and are very satisfactory.

Dr. William Futing T. think that almost any method of treating fractures will answer the pur pose sometimes. However if we discuss methods their val cannot be correctly estimated unless we at the same time specify the particular kind of fracture in which we would employ a particular method.

While the Lane bone plate has fallen into disi vor owing almost entirely t its misunderstood principles and its indiscriminate use by those who should know better, as well as by those who do not, I still believe that this device has a very distinct and an important place in the trestment of fractures.

Instead of the intelligent application of many other measures now at our disposal in fraction work they are entirely misunderstood and are made use of under conditions which are often without the alightest justification. Stremuous efforts at traction and extension are often made where such are not needed, just as they are of least and the last conideration when they are needed.

As one writer has said we individualize too little in our treatment of fractures. No measure yet described is without some value somewhere, but in order to decide furst what procedure should be I-lowed, a careful diagnosis should always be made and every indication accurately determined. Then if we select the particular measure or part thereof which is rightly called for and display intelligence and understanding in the use of whatever that may be the end-results about the satisf ctory.

The nail driven into bone for the purpose of trac tion, as described by D Dyan tonight and by others before this, may have place in the treatment of fractures. But of all the maneuvers yet described I should not besitate to give this one the last place especially when used as a means of affording true tion It necessarily offers some difficulties in placing it exactly in the bone as desired it is in eality an open operation it is light not to hold when great traction is made upo it it establishes a comm nication between an oclean skin at one end of the nail, and a bone lesion surrounded by damaged soft parts at the other end and what is of more importance than all other points combined is the use we can make of older and well-tried methods which call for no operative work and which hold rust as well perhaps better But notwithstanding these objecti ns. D Dyas has shown that the nat can be ad antageously used. The nail for purposes of extension, the Lane plat—the bone plug the transplant, the acrews, the wire, all have some ment and can when judiciously employed be of

Surgeons has a long hoped for a more retional means of treating fractures. That time will probbly not come till the general medical man crases altogether his efforts in this work, and when the general urgeon devotes in re time and thought to it and exercises the same cure and consideration as he ordinarily employe siesewhere.

There are more malpractice rulia brought against members of the profession of ruleir failures to satisfy the public in the treatment of fractures than in all other work combined. Why is this? It is because other surgical work is not done as blindly carelessly and unscentifically as in the treatment of fractures. In surgery of the head of the thorax and the abdome, ample room good expoure and abundant light are demanded. The end results in the treatment of fractures will be no less so when we treat fractures on the same rational basis as is the rule in surgery in other parts of the body.

We cannot all agree with Dr Dyra when he says that the null sticking from the skin surface as he has shown here is as luttle likely to produce an infercion as the open operation. The null hole as virtually a drain track and we are familias with some of the dangers attending these when located near clean wounds. Just how they can be less serious when made by a still transfaring the broken limb and passing out to the surface to be occusionally toyed with as happened in one of Dr Dyras cases, is not clear

In closing I would say that no device or measure should ever be used in the treatment of any fracture simply because it is new but only when they have shown unmistakably that no other device or method can serve the purpose as well. Dr. DANKE, N. ERENDRATH I would take ex-

DR. DAMRE, N. ERRENDRATH. I would take exception to Dr Dyns condemnation of the lack of valu of Bucks extension. If properly applied, B cks extension is of the greatest value. It can

Dr. C. G. Buroun. My experience with fractures has not been small. From the hysteric that has developed on the account of so-called improved methods in the treatment of fractures it might seem to those outside of surpical circles that fractures have been giving us a great amount of trooble and that w. have been laden with damage suits. Such has not been my experience or my observation.

My methods have pretty generally been along the old plans of treatment, namely attempt at simple eduction under angesthesis when necessary and the use of Buck a extension in the extremities when in dicated. Simple fixatio ppliances have been used early and open or closed casts used as perma nent dressings. I think I get as good results as can be blained I have no cripples running around, no complaints from the patients, and have never had damage uit threatened connected with fractures. I rarely use the Lane plate or bone peg. When reductions are impossible and deformities are objectionable I usually do an open operation and poroximat the fragments closing without drain age. Once the fragments are in position it is easy t hold them there. It is the fragments that are not in position which make it difficult to retain them in their proper position I do want it understood that the Lane plate and bon peg, like other good devices, have their places in surgery but since their i troduction I believe as most of you here believe that they invite too many operations and are used entirely too frequently. I have been mazed at the large number of plates and pers reported from the services of men with relatively small amount of work. I feel that the nail brought out by Dr Dyas is a good thing in its place it will certainly have its field of usefulness. I have personally never had

occasion to use it.

The special note which I desire to sound is
Do open operations if you must but leave fewer and

fewer foreign materials in the wound.

Dr. Dr. (closing) I want to give Dr Speed full credit for introducing this method in the treatment of fractures at the Cook County Hospital. He was the first man time! It and with his permiss in I will say that when I began that ork we endeavored to get a group of cases together which would cauble u to mak a report of som value by reaso of the number of cases treated. He deserves full credit for the detailed technique which w have carried out! out work.

I knew my paper would be criticized but if urgens are absolutely satisfied with the way they are going slong in treating fractures and try bothing new they will never make any progress. I feel that our results have justified the work. It is on intention to treat further cases with this method so that x may obtain reliable information. We have not done any infjury to any patient. We have not had infection in single case. We have not had absolutely accurate anatomical results but we have had good functional results.

As t B cks extension, I did not mean to condemn it t the extension I did not mean to condemn it t the extension that some of the speakers do but it is perfectly true from a more chancal standpoint that it is impossible for any one t specific polys as me the fraction by means of adhesive plaster t the skin as can be applied by definite exact traction poparatus, such as the anil and copper wire and pulley extension. Buck a extension has a wholey extension has a whole held of usefulness and always the content of the condemn to t

terious-minded to better their work. Som will results to cate all operative cases by no home feeling that they have so done some become the visiting surreous this result to

presented at the next annual meeting of the Congress. This at times gives a better oppor tunity of estimating the true capacity of a surgeon than does a mere observation of his operative technique. Indeed it is the one criterion of a surgeon a ability and usefulness. Moreover the knowledge that such a report is required may in some instances induce a wholesome conservatism on the part of the operator which is in the main largely to the interest of the patient.

Incidentally Philadelphia has many excellent hotels a medical library at the College of Physi-

cians, second in completeness only to that of the Surgeon-Generals and in its environs, within twelve miles of the center of the city more than a dozen golf links the latter readily made avail able to those who have inclination and time for the game during these busy meetings. It is senreely needful to say that a cordial welcome awaits the guests from the Philadelphia profession who feel honored by the choice made of them atimulated by the hopes bound in them and will remain permanently bettered by assocustion with the broad men from all parts of this broad country

PLANS FOR THE PHILADELPHIA MEETING

On the morning of Monday October 23 in Philadelphia the Clinical Congress of Surgeons of North America opens its seventh annual session. The Congress headquarters at the Bellevue-Stratford will be open for the registra tion of members on the afternoons of Saturday and Sunday preceding and the program for Monday's clinics and demonstrations will be posted

on Saturday afternoon.

The Philadelphia Committee on Arrange ments, backed by the clinicians of that city are Leenly interested to make a complete showing of Philadelphia a clinical facilities in every depart ment of surgery including gynecology obstetrics genito-urinary surgery orthopedics, surgery of the eye car nose, and throat. While the chief attraction will be the clinics in the operating rooms of the thirty or more co-operating hospitals, a series of demonstrations-pathological roent genological borderline subjects, and othershas been arranged by the committee and it is expected that this portion of the program will mrove of exceeding interest.

The clinical program appearing on the follow ing pages is only suggestive of what the Phila delphia climcians have in mind for the week of the Congress. The daily program as bulletined at headquarters will be elaborate and accurate in detail as to the cases to be operated upon or

demonstrated in the several clinics.

These annual clinical meetings have become so popular that the plan of limiting the attendance and requiring advance registration was decided upon to prevent overcrowding. Such a plan has proven successful at the two previous meetings, as it insures accommodations at the clinics for all who hold membership cards. It is evident at this time from the number of registrations already received at the office of the Secretary-Gen rai that the limit of membership for the Philadelphia meeting will be reached some time in advance of the meeting. The limit was fixed after making a careful survey of the operat ing amphithenters, lecture rooms and labora tories of the several medical achools and bospetals as to their capacity for accommodating the visiting surgeons.

EVENING MEETING

On Mo da evening at 8 o clock in the ball room of the Bellevue-Stratford occurs the presidential meeting at which time the officers elected at the Boston meeting will be maugurated The preside tail addres will be delired by D Fred B Lund of Boston the p evident elect. On each of the three following evenings there will be sessions if the section on general surgers in the ball room of the Bellevue-Strat ford and on the same evenings separate meetings for the section on surgery of the eye car nose and throat in another room in the same hotel The program for these evening meetings appears on the following pages. These meetings open promptly at 8 o clock and adjourn not later than 10 to

On Friday evening in Witherspoon Hall at 8 o clock there will be held a public meeting under the combined auspices of the Clinical Congress of Surgeons, the Philadelphia County Medical Society and the Department of Tublic Health and Chanties of Philadelphia to which meeting the public at large is invited.

HEADOUARTERS

The Congress will utilize for its headquarters at the Bellevue Stratford the Ball Room Clover Room Red Room Green Room and adjacent foyers and smaller rooms on the second floor of the hotel providing ample space for registration and ticket bureaus bulletin board etc. the ball room being used for the evening \$85,1008.

The program of clinics and demonstrations for Monday will be bulletined on Saturday after noon, and on each afternoon beginning on Monday the complete program for the next day a clinics will be posted on bulletin boards in headquarters. A printed program will be issued each morning

SPECIAL TICKETS

Attendance at all clinics and demonstrations will be controlled by means of special tickets. The general rule will be that a member may have two tickets for each day one for the morning and one for the afternoon clinics. For cirtain clinics where the accommodations are limited and the demand for tickets is heavy it will be necessary to establish a rule whereby a member may have only one ticket for such clinic during the week. The number of tickets issued for any clinic or demonstration is limited to the capacity of the room in which the clinic or demonstration is to be tiven.

The use of special tickets has proven an efficient means of providing for the distribution of members among the several clinics and insures against overcrowding at any clinic special tickets will be issued each morning at 8 o'fock, for the clinics and demonstrations to be held that day a complete schedule of the days clinics having been posted on the bulletin board on the afternoon of the preceding day and a printed program distributed in the morning

REDUCED RAILWAY INDIS

The railways in the states east of the Mississippi River excepting the southeastern states south of the Ohio and Potomac Rivers and in the eastern portion of Canada have granted certain reductions in fares in selling round trip tickets to Philadelphia on account of the Clinical Congress of Surgeons. Round trip tickets will be sold at the rate of two cents per mile in each direction going and returning by the same route only and over which one was tickets are regularly sold. Tickets will be on sale from points within the territors specified on October 21st

22nd and 2 rd with a general return limit to reach me's original tarting point on or before midnight. November 1 t

In particular these reduct I rites will be in effect in the territory covered by the rulway lines in the New Fugland Passenger Association Trink Line Association Central Lassenger Association and Ea tern Cana him Lassenger Association Anapplication for the granting of the same reduction in fares by the lines in the southeastern tates is now pending in 1 probably will be acted upon flavorably.

Members living in the states west it the Missippi Kirer and within the territory overed by the Western and Southwestern Pisenger Association that is west of Chicip, in 1 St. Louis should purchase tickets to those gat way and then repurchase round-trip tickets to I hila deliphia in order to avail themselves of the reduced fire.

The Baltimore and Ohio Railroad is prepared to ther members of the Congress from Chicago and the West attending the Philadelphia meeting special service on train leaving Chicago at 5.45 p.m. Saturday October 1st arriving Philadel phia at 5 to Sunday evening and on train leaving Chicago at 1045 Sunday morning arriving I hiladelphia at r m Monday The Michigan Central Rulroad in connection with the Lehigh Valley and the Philadelphia and Reading offers pecial service on its train leaving Chicago at Jos Sunday morning arriving Philad lphia 9 15 From the Northwest the Months morning Great N rthem Railway is making arrangement for the benefit of member living along it lines while from the Southwest the Atchison Tipeka and Santa Fe will likewije offer special facilities

MEMBERSHIP - RECISERATION FLI

The Constitution 1 the Congress provides that all subscribers to the official journal Surgers (End General 1997) of the Congress and that such other legally qualitied practitioners as are in good standing in their own communities may become members upon registering at an innual meeting. A registration fee is required of each member attending an annual meeting there being no annual dues for members of the Congress. The registration fees provide funds to meet the expense of preparing for and conducting the annual meetings so that no financial Furdin is imposed upon members of the Opinges.

CASE N 6703. Age 14 F Came for relief of focal epilepsy and blindness. Pre-operative diagnosis focal epilepsy (left arm) Operation Oct 5 ether Dr Harvey Cushing, esteoplastic exploration of right hemiphera. Post-operative diagnosis same old meningo-enerphalitis. Complications, none. Discharged N 5 condition uncharged. Late result, June, 9 6 condition unchanged.

Case No. 6857 Ag 58 F Cam for relief of pain in, and enlargement of, abdomen. Pro-operative diagnosis, overlan cyst. Operation, Oct 3 other Dr John Homans, exploratory laparotomy Post-operation diagnosis, general carcinomatosis, large mass in left belomen, carchouns of omentum. Complications, none. Discharged Nov 18 unimproved. Patient died M 8 o 6 syldently of the disease found at operation

topey Case; No. 6835 Age as F Came for relief of pain and frequency of mictorition pain in right lumbs No. 6835 Ago at F Came for relief of

region. Pre-operative diagnosis, tuberculous pyonephrous Operation, Oct 5 ether Dr David Cheever right ne phrecton Post-operative diagnosis, same. Complica tions, none Discharged Nov o improved. Lat re

sult, patient could not be traced.

SMIT, patient count not be tracet.

CASI A. No. 6033. Age so T. Came for relief of swelling in left groin 1 years duration. Pre-operative diagnosis, left inguinal hernia. Operation, Oct. 5, ether D. David, Cheever chasers of direct inguinal hernia. Post-operative diagnosis, sam Complications, none Discharged Nov 8 relieved. Lat result, patient could

not be traced CARE 5. No. 6830 Age 35 F Came for relial of lump in right breast. Operation, Oct. 3, 9 5 for local removal of tomor reported benign at first but later proved to be mailroant by microscopical examination. Fre operative diagnosis, carcinoms of breast Operation, Oct. 46, 46er Dr. Devid Chevrus eccondury exemion of perioral nuncles, with dissection of dilla. Post-operative diagnosis, same. Complications, secondary skin graft 15 day after operation. Discharged Nov 5 relieved. Lat result, patient reports by letter that there is some welling and weakness of arm local doctor report no

evidence of return of the discuss.

Case 6. No. 6939. Age 58 M. Came for ellef of difficulty in walking distincts, beadache, and conversions. Pre-operative diagnosts, tumor of right cerebral hemsesphere. Operation Oct. só Dr Harvey Cushing right subtemporal decompression. Post-operative diagnosis, same. Complications, condition excellent until 7 hen severe epslepelform ttack occurred with death within a short time without regulning consciousness

Autopay endothelloms of the brain (right frontal lobe) probably operable subdural hemorrhage talt of decompression wound beginning bronchopneumonia arterioscierceis.

Vets. On the morning of operation, the patient had Facksonian actsure, involving his left hand and doubtless had the Congress not been present, this would have been brought to the iteration of the operator and the operation postponed. Under these dreumstances, subtemporal decompression was an incorrect measure, and he should have had an outcoplastic resection exposing the hand center which would have duclosed the tumor an easily exudeshi growth. It is the sort of accident that is more tikely to occur under the press of work while entertaining large body of visitors, and is one of the reasons why I feel that on the whole, though these Congresses may be instructive to the colooker they often put the patient at

dradvantage - H C

CAST 7 N 6000 Age 45 F Came for relief of varicoss veins and ulcer 30 cans' duration umbilical kernas Pre operator diagnosts, same. EDITORIAL ANNOUNCEMENT

A consideration of the various methods of shortening the uterine hyaments, as a surgical cure in uterine displacement has been alway an interesting subject and one extremely debatable during the past twenty two years. In this time the subject has been reviewed academically at intervals and in every Instance a consensus of opinion has been sought regarding the relative merits of the various methods of ligament shortening that have been a liveracted. Since the review by Alfien in 1911, no unprejudiced and comprehensive discuss in a fitne subject has been offered. With considerable satisfaction therefore a unmounce such a discussion of the present status of round ligament in returning in the form of a critical review for the next number of the Interestant sate. In traver of Studgers, The author Sidney A Challant of Phitsburgh has brought to bear upon this theme not only the substance of an extensive literature but also a justical stituted developed out of experience in the ward and precising in

especially after the fourth decade producing a disproportion between the lens and the total size of the eye as compared with the proportion in earlier life. In brief the glaucomatous state is brought about by a crowding forward of the ins against the posterior surface of the comes at its perinhery with a consequent blocking of the exit of the squeous fluid from the anterior chamber into the canal of Schlemm at the aderocorneal margin. The hypertrophy of the overfunctioning cliary muscle in the hypermetronic eye favors the blocking of the iris angle thus hypermetropia. is a predimoung factor in glaucoma. Obviously an inflammatory exudate from the uveal tract produces an excess of intra-ocular contents and such exudate may clog the channels of exit.

Thomson Henderson (3) has advanced a theory of glaucoms within the past decade which has aroused much interest. He believes that the pectinate ligament at the angle of the anterior chamber is a cellular structure in early life and becomes progressively aderosed with advancing age as a result of the influence of the constantly contracting ciliary muscle, to which he believes this ligament serves as a base of attachment. This scienosis cuts off the exit of the acueous and places the responsibility of ocular drainage upon the tris veins which may be madequate to this excessive demand. In the absence of other causes - vascular nervous, or biochemical -no increase of tension will occur, but the sclerosed structure at the iris angle furnishes an anatomical basis for hypertension according to Henderson, when precipitating causes arise. There is frequently a connection between glaucoms and high blood pressure, but the extent to which general arterial hypertension is responsible for ocular hypertension is still in daspute. Intraocular hamorrhage may of course, precipitate a glaucomatous attack.

There is no manimity of opinion as to these various theories, and we must be content at the present time to say that an imbalance between the formation and exerction of intra-ocular fluids, normal or abhormal, gives rise to hypertension of the globe. Variations in intra-ocular tension are quickly compensated for by wanations in out flow under normal conditions. Numerous factors may impede drainage and came hypertension. In the words of Priestre's Smith, glaucoma signifies an excess of pressure within the eye, plus the causes and consequences of that excess." It is not a disease entity but a term applied to a symptom-complex which may be the manifestation of a van ty of diseased conditions. Indeed, the symptom-complex uses within wide limits, the symptom-complex uses within wide limits,

from the violent inflammatory glaucoma to the simple chronic form of insidious character which some observers would not class as properly the same disease. Moreover glaucoma may be the direct result of a pre-existing or coincident inflammatory process or trauma of the eye (secondary glaucoma) or may be independent of any other demonstrable disorder of the eye (primary glaucoma). A distinct type of the aymptoncomplex is congenital or infantile glaucoma (hydrophthalmos or buphthalmos) in which the eye is greatly enlarged by stretching of its tunics in intra uterine life or in maney.

With many kinds of eye disease, varying in cause and clinical course, classed together under one name because of one common symptom, increased hardness of the eveball and with simple glaucoma remaining one of the mysteries of medical science, it is natural that many kinds of treatment have been tried and none found successful in all cases. The fact that glaucoma is a manifestation not merely of a diseased eye but of a discased body as well is being emphasized and a more comprehensive study of these cases is being made than in former years. While awaiting the establishment of a definite ethology and an effective prophylaris it is the difficult task of the conthalmic surgeon to seek to obtain per manent drainage of the ocular fluids and avoid certain dangers incident to the maintenance of the drainage. The reports of efforts to accomplish this task fill the pages of ophthalmic literature of recent years.

The surgery of glaucona is discussed at length in the many testbooks of ophthalmology and with especial fullness in the American Engacopedia of Dphthalmology (a) in which the following convenient classification is made (1) operations on the network of the globe, and (3) operations on the atterior half of the globe, and (3) operations on the sympathetic system of nerves. A brief consideration of the dider operations under these three headings will serve as a background to a more critical study of the recent extensive literature dealing with newer operations.

1. Operations on the posterors half of the globe counsit in puncturing the tunics of the eye (sclera, chorked, and retina) for the purpose of allowing the escape of some of the vitreous humor This procedure affords a rapid decrease in Intraordar tension by lessending the intra-ocular contents but is transfert in effect as the wound quickly heals. Confrin of Lyons is credited with this operation of posterior scientomy as far book as 1769. As now performed the operation usually requires only local anæsthesia (cocaine) after which the conjunctive is grasped with for ceps near the sclerocorneal limbus and the globe rotated so as to allow the entrance of a Gracie cat aract knife as far back as possible into the vitreous chamber A quick puncture of the tunics passing the knife several millimeters in and a slow withdrawal give the minimal result namely the escape of a small bead of vitreous. A somewhat greater immediate effect and also a more prolonged effect is obtained by an L-shaped incision in which the knife after the puncture is rotated on its long axis oo and withdrawn so that two linear cuts in the form of a letter L are produced This wound allows more gaping and heals more slowly than the simpler incision first described.

The simplest of the many operations on the anierior half of the globe aims to accomplish the same result. Paracentesis of the cornea is per formed by messing this membrane just within the sclerocorneal limbus with a small keratome or a Desmarres needle which is a small lance with a thickening at its base to prevent the needle s entering beyond the desired distance. Slow withdrawal of the instrument with gentle pressure against the posterior lip of the wound allows the anterior chamber to empty Local anaesthesia is often sufficient for this as for the preceding operation, but very high tension with engorgment of the ocular circulation diminishes the effect of local anæsthetics and therefore safety sometimes demands the use of general anæsethsia. Miotic drugs, as esenne, are practically always used both before and after these operations. The corneal wound can be opened by gentle manipulation with a small spoon or spatula and the effect of the operation renewed for several successive days in this way

Such transient lowening of tension is of service in the presence of a presumably transient hy pertension where permanent relief may be expected in a few hours or days as in the secondary glaucoma occurring in the course of an iridocyclitis or traumatic cataract when the filtration angle is blocked by uveal exudate or lens matter or blood. In acute inflammatory glaucoma with a very shallow anterior chamber posterior selerotomy reduces tension and deepens the anterior chamber sufficiently to allow indectomy to be performed with safety. It also serves to relieve pain in absolute glaucoma, and to reduce tension temporarily in both acute and chronic secondary glaucoma.

Iridectomy The very bnef duration of the beneficial result of these simple puncture operations limits their usefulness. The procedures

promising a more prolonged effect constitute the bulk of the operations performed upon the anterior half of the globe. Of these, the classic indectomy of you Gracie (1850) has been men The detailed description of the opera tion is available in the textbooks and need not be repeated here. It is necessary however to consider some features of this operation at length in order to understand the present-day problems of glaucoma surgery Indectomy is so important an operation that every other method of re ducing intra-ocular tension has to bear rigid com parison with this time honored procedure. It is also noteworthy that the excision of a piece of the iris is one step in many other operations whether an essential or a negligible step is a question which concerns us greatly

The use of miotics and in the presence of an acute glaucomatous attack a preliminary poste mor selections increase the safety of indectomy Local anæsthesia suffices in non-inflammatory cases but general anæsthesia is necessary in the inflammatory type where tension is very high and but little effect is secured from cocaine. A wide keratome is preferred by most operators except when a very shallow anterior chamber makes it difficult to pass a keratome between the cornea and lens without injuring one or the other In this case a narrow Graefe cataract knife is used. The incision is regulated so as to open the angle of the anterior chamber which is posterior to the visible sclerocorneal limbus. Unless this is accomplished the iris cannot be cut or torn at its ciliary attachment or root and the purpose of the operation is defeated. Therefore the incusion and the indectomy are essentially different from the procedures used when indec tomy is performed for optical purposes and as a preliminary step in the extraction of cataract. Bearing in mind this important difference the surgeon begins his keratome incision 2 mm back of the upper limbus piercing the sclera with the blade nearly perpendicular then depressing the handle as soon as the tip of the keratome is seen in the anterior chamber and pushing the blade forward between the corner and iris in the plane of the latter until the incision is o or 10 mm. in The keratome is then cautiously with drawn allowing the aqueous to flow out slowly The incision may be lengthened by pressing the edge of the keratome against one angle of the wound while withdrawing but it is desirable to make the entire incision while the keratome is ad vancing through the anterior chamber unless the shallowness of the chamber makes sufficient ad vance of the instrument dangerous to lens and

difficult to formulate any generally actheory as to the ward in which iddectomy i cure of glaucoma or the limitations to to the use of this operation. That the of iris back to its root removes the obn to the exit of intra-ocular fluid through are of Fontana at the iris angle is perhaps t widely accepted explanation. That the a of the lirk do not adhere but remain as a ace allowing drainage of the aqueous into youn is an observation which bears upon

this question. It has been maintained that the iridectorny is an unimportant feature of the operation and that the flect is in reality at tributable to the scleral incusion. It should be emphasized that indectomy aims to reopen the natural channel of drainage is contrast to some of the more recent operations which attempt to produce new hannel The most positive state ment which one ca make about indectomy is that it has a tire em nent place in the relief of acute inflammat rv glau sna. Whether the newe operat as will r pla e iridectomy in this class of cases emains to be seen but for the present no other in that fill toring the balance of atra-ocular cir ulati a show equal results. The earlier the parat in the more uccessful the result. When betruction of the imangle is due to vascular congestion and not to permanent adhesion f ris to cornea, as in the chronic type of glaucoma in lectomy removes the batruction. In subacute glaucoms the flects are somewhat less sure. In the bron c form (simple glaucoma) the results are not sufficiently uniform to give satisfaction. The tatu i reflections in acute glaucoma is nd cated by the tabulation of Wreed ki (c) showing a fa rorable outcome in 80 per cent of all cases. In glaucoma simplex statust cal report lack n formity Hallauer (6) found te is n reduced to normal in 80 5 per cent of cases with recurrences n 31 per cent Von Hippel (7) bil es that ridectomy is ne gently called f a the surest means of combating glasscoma. De Wecke (8) found that nine tenths f a group of 20 ophthalmic surgeons favored ridectomy i glaucoma simpley while the remaining one-tenth considered it comparatively useless. In hamorrhagic glaucoma and huphthalmos iridectomy is disappointing A per sistent effort has been made to find more effective operative procedures for these less favorable types. These methods concern chiefly the drainage of the aqueous and therefore belong in the chastlication of operations upon the anterior half of the globe. They have been conveniently divided into (a) operations which attempt to effect a communication between the anterior chamber and the subconjunctival spaces (b) operations which attempt to effect a communical tion between the anterior chamber and the vitreous and (c) operations which attempt to produce drainage through the chorloid and the suprachorioidal spaces.

a. The operations which attempt to effect a communication between the anterior chamber and the subconjunctival spaces are based upon the

two procedures already discussed paracentesis of the cornea and indectomy Thus de Wecker practiced anterior sclerotomy (1867) in which substantially the incision with the Gracie knife as used in the indectomy operation is made but a bridge of tissue 2 mm wide is left intact behind the upper limbus to prevent prolapse of the ins In this way a filtering cicatrix is utilized for securing additional drainage at the angle of the antenor chamber. De Wecker considered this procedure a valuable preliminary step to iridec tomy when the anterior chamber is very shallow He preferred it to other operations in combina tion with miotics in chronic glaucoma and in the other types of the disease in which indectomy is not highly satisfactory as harmorrhagic glaucoma and buphthalmos and as a means of reducing pain in absolute glaucoma. The operation has not been used extensively in recent vears. Various modifications of it were made with the addition of incision into the ins tissue Panas (9) (1884) practiced iridosclerotomy in which he passed the knife through the ins from before backward traversing the postenor cham ber and again piercing the ins before making the counterpuncture Knies (10) (1893) used a keratome and attempted to produce an indochalysis pulling the iris away from its ciliary attachment. De Wecker accomplished the same result by tearing the iris with forceps passed into the anterior chamber De Vincentus (11) (1893) used a sickle-shaped kmie with a convex cutting edge, sweeping around the angle of the anterior chamber cutting the tissues to a depth of 1 mm or more. Obviously these several methods have the common aim of the original indectomy operation and all endanger the crystalline lens none of them has become popular b The observation that excess of intra-ocular

fluids exists mainly in the vitreous chamber as evidenced by the bulging forward of the iris from pressure behind it, has led to attempts to effect a communication between the anterior chamber and the vitreous in order to restore normal depth to the anterior chamber and open the iris angle. Thus Chibret (12) (1898) prac ticed sclero-cyclo-indic puncture, using a double edged Gracie knife entering 3 or 4 mm behind the limbus and passing obliquely through the sclera into the angle of the anterior chamber The iris was pushed forward by the knife and its ciliary attachment loosened This procedure was repeated in 5 or 6 mendians. Severe hamor rhage into the anterior chamber is a disadvantage in such an operation Sclerotomia anteroposterior has been done after un ucces ful indections. A Graefe knife is introduced into the anterior chamber and passed backward through the coloboma into the vitreu. The practically limited to use in blind eves where injury to the cry talline lens, negligible. Herri (13) (1869) practiced of rico-indo-vitre use punctur after indections. A very small Criefe knife is passed through the coloboma to the circum lental space and literal in venicin made to widen the cut. All these included are so han gerous as to be practically limited to eves in which vision is already lost. They like the procedure

c. The attempts to produ e diamage through the choroid and the supra herioi lal spaces have differed somewhat from the rreview or up Here the effort has been to sever the attachment of the citiary muscle to the sclem. Hancock (ra) used a Beer's knite enturing at the sclerocorneal limbus bel w and temporally and in cising the sclera obliquely backward f r more than one-eighth inch. Walker used a narrow knife entering the cornea just within the limbus with the cutting edge directed away from the anterior chamber. Thrusting through the base of the ins he withdrew by cutting out through the sclera. Querenghi (15) (1000) attempted by means of a scleral incision with a narrow knife to enter the posterior chamber and to incise the choroid by sawing movements from within out ward These operations are dangerous and de serve mention only as predecessors of the more

important recent measures In addition to these many operations upon the eveball brief mention must be made of (3) operations upon the sympathetic system of nerves The operation of excision of the superior cervical cancion was based on the observation that sec tion of the sympathetic results in a soft eye which seems to have been known as long ago as the early years of the eighteenth century effect of cutting the ganglion is greater than that of cutting the cord but both are temporary The influence is probably vascular and muscular through Mueller's muscle at the apex of the orbit. Jonnesco (16) (1800) removed the superior cervical ganglion by means of an incision parallel to the anterior border of the sternomastoid muscle opposite the angle of the jaw dissecting between the carotid artery and vein until the ganglion is exposed behind the artery. The ganglion is freed from its surroundings and cut with scissors the ascending and descending cords are cut likewise. Though favorable results have been reported the effects are not permanent and several deaths have followed. Excision of the ciliary gangion has also been attempted Rohmer (17) made a Kroenlein resection of the outer wall of the orbit divided the external rectus muscle and passed forceps along the side of the ontic nerve attempting to grasp and crush the ganglion. The operation is difficult the actual destruction of the minute cancilon embedded in orbital fat uncertain of accomplishment and the operation has not found favor in spite 1 some reported successes. Avulsion of the infratrochless nerve was attempted in 1861 by Badal (18) to relieve pain in glaucoma, the results were temporary All of these procedures have fallen into comparative denise and in the literature in recent years no tendency is shown to attack the glaucoma problem from the direction of the sympathetic nervous system

One new operation upon the posterior half of the globe deserves mention. In 1913 Wicher klewicz (10) suggested what he termed scleratems rucials multiplex where operations upon the anterior half of the globe had failed in securing permanent result. He exposed the sclera extensively by dissecting back a large flap of confunctive and Tenon a capsule and made from four to six parallel meridional incisions with a Graefe knife as far hock as possible, each to to re mm long, through the sclera, and then as many more incisions at right angles to the first senes. The flap was then sewed into place. Immediate massage enhanced the effect. This operation seems to have made no headway in the presence of the many rivals now attracting attention.

Heine's eveledualysis (20) is of more importance. The one method of securing drainage through the suprachodoidal spaces which has obtained favor is that devised by Heine in 1905. He seems to have received the suggestion from Fuchs observation that detachment of the chorlold some times follows entaract extraction and iridectorny and occasions a subnormal tension. Under local ancethesia a large conjunctival flap is dissected up from the lower temporal quadrant A 2-mm. cut through the sclera is made 5 mm. back of the limber and parallel to it. This incision is made carefully with a keratome to avoid injuring the uveal tissue beneath. The black color of the uvea indicates that the sclera has been penetrated. A spatula, slightly curved at the end is named gently within the scleral wound and worked forward between the sclem and the ciliary body with its plane parallel to these structures until the tip appears in the anterior chamber. Sweeping the patula from side t side widens the tunnel beneath the sider. Homorphage from the antern reliant vole is a complication which atest are with the good results of the operation unless the libert absorbs quickly injury to the lens must be arrially guarded against. The

niunci al flag i repla ed and triched. Merener and Sattl reported 54 operations, concluding that prelockal us is designed especially for throni glau oma but that it exhibits no marked diff renk in effectiveness from iridec tomy. They emphasize the danger of humor rhare from the anterior ciliary vessels. Knapo thought after an sperience of 18 cases that the operation. not an adequate substitute for

undecte my Of chief interest among the innumerable procedures suggested for the relief of glaucoma, in addition to sclodulyus are those which have come into vocue in the past decade as a result of dispatisfaction with the older methods of treating the chrome types of glancoma in which iridectomy is of uncertain value. Gradually the opinion that a soundly healed cicatrix possesses filtration properties has lost favor and operators have attempted to produce a permanent path of exit for the aqueous through the scienal trasue by creating a cystoid cleatrix. Two special methods of producing this are by the use of a trephine to remove a button from the sclera, and the deliberate incarceration of ma turne within the ademiwound. Thus the never operations may conveniently be studied under the three headings of (1) evstold elentrix, (2) trephine operations, and (a) incarceration operations.

1 Crstold cicatrix The first important operation devised to obtain a cystoid cicatrix was the subsiderectomy of Lagrango (ss) (1906). After the use of eserine and local annestheria a Grante knife is used as in the operation of indec tomy puncture and counterpuncture being made well back of the limbus. The knife is turned backward on completing the incision above and emerges very obliquely behind the upper limbus making a large flap. The sclera contained within this flap is then cut out with fine curved scissors An indectomy is made and the conjunctival flap replaced Lagrange at just advised indectomy in all cases but later limited its use to cases in which there seemed to be danger of prolapse of the iris if left intact. He holds the operation to be especially adapted to simple chronic glauoma and has protested against its unlimited use in all varieties of glaucoma. The thickness it sclera removed may be regulated according to the amount of weakening degred in the sclera, the amount of sclera excised being in inverse propor tion to the degree of hypertension. A valuable discussion of the merits of the Lagrange operation was made by Ballantyne in 1910 (3) Further consideration of it will be given by comparison with some of the other procedures to be described.

Hoth's (6) punch forceps operation is an important modification of the Lagrange method. In order to lessen the size of the scleral opening and to regulate the excision Holth made a less extensive incision and having dissected away the conjunctiva from the underlying sclera of the anterior lip of the wound he removed a bit of this scleral flap with punch forceps. The excised sclera measured 3 x 1,5 mm. This operation has been practiced with much success Butler (24) prefers it to any other on account of ease safety and quickness of execution.

In 100, Herbert (25) described what he termed the wedge isolation operation which he considered superior to the Lagrange in that the incision is shorter the indectomy smaller and the amount of scleral excision better regulated. This operation has not gained favor to the surprise of those who have witnessed Herbert's results probably because of the difficulty of gaining a dear idea of the minute details from a written description even so carefully and fully stated as Herbert's own description. The following brief resumé will indicate the difficulty Graefe knife ground down to a breadth of less than I mm. is used. Puncture and counter puncture are made high up so that the anterior chamber is traversed for only a short distance in its upper portion. The incl. ion i continued upward and backward until the sclera is cut through but a bridge of conjunctiva is lett un cut The knife is then pushed back into the scleral wound and turned upwill and forward so as to make a second cut through the sclera from behind forward. This serves to islate a wedge of sclera with the apsy toward the anterior chamber. Subsequent hinding, to the wedge leaves a nitration area. Every mall peripheral infections to made without then cessity for thing the bridge of onjunitive at ve. Herbert hirst report indicated tay and for cut in Science.

Tr blin perati n Arrall Kolsettein () used a selfal treplane fatty var ag Strawl ridge of I hiladelphia H we i Buttil and Ir which also used to han in trument but the crocedur seem to have tundin to or until Fergu (8) used it in connecti in with 3 I hal var. He h sected community didar up to the corneal margin in Libercith it made a fr Thine cpening through the seletant in mm back of the H then pa sed a patula through the opening and separated the select trim the ciliars body and the iris until the spatula appeared in the anterior chamber Som contuin hi arisen between the and the trephine operation of Elliot The latter 1 sometimes called the Forgus Elliot operation. The facts are that hereit practiced his operation independently of Filiot and before Elhot's first publication (1900) but did not de scribe it in the literature until a few months later and of more importance, the two operations differ in such essential teature, that there is no nistincation for confusing them. Elliot makes the trephine opening in the corneoscleral junc tion entering the anterior chamber and making an indectomy Fergus trephines entirely in the sclera and enters the antenor chamber only after tunneling between the sclera and the uveal The route for the evacuation of aqueous is different in the two cases

Elliot's operation (o) was developed from a large experience in the British medical service in India He dissects up a large conjunctival flap with the base at the upper sclerocorneal limbus. Reflecting this flap over the cornea and holding it with forceps from below he steadies the globe and continues the dissection with blunt scissors going between the lamellæ of the cornea so that the trephine can be placed astride the limbus and the buttonhole include corneal as well as scleral It is essential that the dissection go be low the superficial tissues getting well down to the sclera proper in order not to buttonhole the con junctiva. The trephine hole is or 2 5 mm in diameter Various models with handles constructed for the convenience of the operator, and with chameters varying from 1 5 to 3 5 mm have

been manufactured. Holding the trenhine over the limbus, making sure to include the corner in the incision, the cutting edge is inserted by means of a few twists of the fineers. Further revolving of the instrument effects a masage through the sclera. Experience enables one to be sure that he has entered the sciera without withdrawing to inspect the incision. Firmness in holding the instrument and the use of very little force are necessary. The sensation of resistance to the instrument coases when the trephine cut is complete and aqueous wells up around the treplune. Elliot makes slightly more pressure on the corneal side of the incision so as to be sure of going well forward and entering the anterior chamber. Thus a hinge may be left on the scieral side of the incision and hold the button which in this use can be removed by one saip of the sussors. This same unip of the scissors may also be utilized for accomplishing a small peripheral indectomy if the iris presents in the buttonhole. Filiot did not at first regard the indectomy as an important feature of his operation in fact he has no er at tempted to make the type of indectoms described in the classical operation but practically he finds that a small peripheral indectomy is useful in preventing prolange and consequent obstruction of the trephine opening. The conjuncti al flap must be carefully replaced. Some operators prefer to secure the flap in place by «titches but it is generally considered sufficient to stroke the flan with a spatula until it is thoroughly spread over its original bed. Eserine is ustilled if the ing tends to prolance otherwise no drops are used. The anterior chamber remains shallow for a long time and the tension correspondingly low A bleb of conjunctive indicates the site of the ecleral opening

Fox (to) has utilized the Van Lint sliding flap making a quadrilateral flap of conjunctiva with the attached base at one side so that the flap can be drawn over the upper portion of the cornea. covering the trephine opening, and sutured at the opposite side. David Priestley Smith (3x) uses a keratome instead of the trephine and makes a triangular incision in the anterior in of the kera tome wound by means of two converging cuts of the scissors, so that the apex of the triangle points toward the center of the cornea. Elliot in several later contributions has defended his operation for practically all varieties of glaucoma. He now makes an indectomy in all cases and uses atropine to forestall the "quiet intis which is likely to occur He objects to the silding flan. He does not admit that the technical difficulties of the operation are beyond the skill of the moderately experienced ophthalmic surgeon.

1 Incorceration operations Curiously the accident against which ophthelmic surgeons have always guarded namely the incarceration of ins tisaue into the scar of a scleral or corneal wound has been practiced deliberately in recent years. Several observations have led to this. It has been trenuently noted that such incarcerations left the tension permanently lowered and that aqueous leaked into the subconjun tival space that in dectomies f r glaucoma in which the operation was technically most imperfect tris being entangled in the wound gave very actisfactory results, and that the danger of infection is minimized it the prolapsed ires is covered by conjunctiva Therefore several urgeons were build enough to attempt to incarcerate the iris in a small scieral wound. Herbert (1) has discussed the subject fully in the English literature and has described several procedures in which he has incarcerated iris and also conjunctive in the scienti incision. Holth (13) has practiced with much success his operation called ridencleists. He makes a ery oblique keratome inclaion beginning far back of the upper hmbus so as to have a broad layer of conjuntuya. After a small perinberal tridectomy he draws a fold of iris into the wound and lea es it covered with conjuncma. The anterior chamber remains empty for a long time. Various modifications of this method have been made. Most of the reports are less in orable than those of Holth himself who records 75 to 85 per cent of cases with satisfactory cystoid scars. Schioetz, on the other hand, obtained only \$8 per cent of satisfactory scars

Borthen's undetasts (14) is the most important modification of Holth's method. Borthen does not incise the iris but draws it into the wound so that the posterior surface of the ins lies against the conjunctive with the sphincter well beyond the scieral opening. He uses atropine so that the sphincter will be paralyzed and not tend to draw the irls within the wound. This operation is not advised in the presence of an atrophic iris. Comparison of 26 cases of iridotasis with 26 done by Holth's method convinced Borthen of the superiority of iridotasis. Roy (35) has reported favorably on 9 operations after Borthen's method. He emphasizes the importance of a small opening into the anterior chamber just enough to admit the less forceps so that the his is held within the wound and does not allo back into the anterior chamber Roy has not used atropine he is

pleased with the simplicity of the operation and the lack of post-operative irritation. He quotes a personal communication from Borthen stating that the latter has performed tridotasts 242 times since 1008 and finds no need of using any other method. Botthen considers the good results due to the increased drainage through the spaces of Fontana in consequence of the stretching of the ins rather than to the type of cleatrix. Mayer (36) has sought to accomplish the same end by making an iridodialysis through pulling on the ins with two pairs of forceps and placing the loop of ms thus torn from its base within the scleral wound. He leaves it so for one week when he cuts off the protruding part. Harrower (37) records 7 cases of indotasis with good results in every case

Foreign-body drains Another type of glau coma operation which promises some usefulness is the insertion of a foreign body drain beneath the conjunctiva and in the anterior chamber Mayou (38) in 1912 utilized a short thread with a knot tied in it. He pushed the knot into the anterior chamber leaving the two ends of thread in the subconjunctival space with the flap of conjunctiva carefully replaced over it. Zorab (30) in the same month reported his operation of aqueoplasty which differs from Mayou's opera tion only in the fact that the loop of thread passed into the anterior chamber has no knot in it. The gradual absorption of the thread is thought to leave a fistulous track for the drainage of aqueous into the subconjunctival space. Casey Wood (40) (1915) has modified these procedures in the following manner He uses a narrow Graefe kmfe with a hole in the end of the blade like the eye of a needle. After puncture and counter puncture in the usual way he threads the knife blade with silk and withdraws it through the same openings leaving a double thread in the antenor chamber The loop of thread is now cut, freeing the kmfe thus four ends of thread are left two on each side which are threaded to small curved needles. Each needle is passed as far as possible through the episcleral tissues, each in a different direction Each thrend is now cut at its emergence from the conjunctiva. Four paths of cut for aqueous are thus made by the gradual absorption of the sill. Arthur Prince (41) makes use of a gold horseshoe shaped wire passing it into the anterior chamber with the ends resting in the scleral wound which is made by either the Lagrange or Elliot method Vail (42) has recently reported an experience in 1907 with a case of absolute glaucoma in which he in

serted a silk thread through Tenon—capsule into the vitreous. This resulted in normal tension and absence of pain for a period of two vers until the patient's death. Vail suggests the advantage of utilizing a natural channel of drain age such as Tenon's space and availing a thin conjunctival covering.

These operations offer the the retreal objection of a foreign substance left within the eve which may excite inflammat by reaction. More time must clapse before any opinion can be expressed in regard to their effectivene, and safety.

This resume by no mean exhault the list of operations suggested for the relict of glaucoma. It merely covers the more important procedures which are practiced at the present time together with some which are too new to almit of any conclusions. It would be a bold attempt to pass haal judgment on the popular peration which have been described indeed loginatus statements on the surgery of glaucoma are devided out of place. One may hope rather to point out soft place. One may hope rather to point out soft persent the tayoral is and unfay rable expenences with the several types of operation now in vogue as they are recorded in the literature.

The simple procedures as posterior sclerotomy and paracentesis of the corner still have a place and probably always will as valual le temporary expedients for lowering intra-ocular tension until certain transitory causal factors of hypertension cease to operate and as a preliminary to more radical measures Massage of the globe deserves a place among these temporary measures. The fulminating type of glaucoma sometimes requires such preliminary treatment before in dectomy can be safely done. The secondary glaucomas can be tided over by such comparatively simple measures until the primary condition is brought under control. The severe pain of absolute glaucoma may be relieved by evacuation of ocular fluids and enucleation sometimes avoided Acute exacerbations in chronic glau come can be likewise bandled

Inflammatory glaucoma has always been the most favorable type for cure by indectomy. This type is of the nature of an inflammatory cedema shutting off the exit of aqueous by the apposition of the ins to the corrica at the angle of the anterior chamber. Removal of a large piece of ins well back at its ciliary attachment is a logical means of removing this obstruction. Results are prompt and permanent in a large majority of cases. It is reasonable to expect

a degree of vision nearly equal to that which existed previous to the attack. The earlier the operation the better the prognosis. An atrophied it is contra indicates the operation, as does a very much contracted field of vision.

If all claucoma were inflammatory the search for operative means of controlling t would probably have cope no further but the less favorable results of indectomy in sample glaucoma have created a need for other operations and these operations have been tried also in the inflammatory type. These facts illustrate a tendency not altogether fortunate, to extend the use of surgical procedures beyond the purpose for which they were first designed and to bring disrepute upon measures which are entirely proper when not musclaced. Thus the Elliot trephine operation and the incurrenation methods have been praticed, not only in simple charcoma, n which there has been urgent need for some more effect ve treatment than indectomy but also in acute nflammatory glancoms. Such a series of cases as that of Gross, 237 cases, in which of percent of those indectomized in the prodromal stage and 87 per cent in the acute stage were successful would convince most surreons that no more is to be expected from other types of operation than from iridectomy On the other hand the results of some of the newer operations would justify their use by operators who have mastered their technique if there were no greater dangers ineldent to these operations than to indectomy Unfortunately however there is the danger of subsequent infection through the thin co error of confunctiva which is the only protection to the interior of the eye in the operations which secure a cystoid cicatrix. It is too early to say just what place these operations may come to occupy in the treatment of acute glaucoma but for the present it seems wise to depend upon ridectomy in this type of case rather than to risk the danger of late infection after another operation which has not yet proved its superiority. Thus Butler and Evans (43) report a series of 70 cases of acute and subscute glaucoma in which normal tension was secured in 88 per cent after iridectomy and in \$2 per cent after various of the newer scieral operations. In the latter cases these authors call attention to the accompanying indectomy which they believe to be the secret of the good results.

Certain cases of inflammatory glaucoma present technical difficulties to the performance of indectomy and Henre's cyclodialysis may be utilised instead for example the fulminating type in which the anterior chamber is obliterated and an indections is impossible and when old people must be operated on who cannot be safely kept in bed. Cyclodialysis is not to be regarded as a satisfactory substitute for ridectomy but may be a necessary expedient to secure a greater effect than the simple punctures of the aders or corner.

Glaveras in Mrs. presents a larger and more difficult problem. This is not the place to enter upon a discussion of the relative ments of medical and surgical treatment for this type of glavcorns. Suffice it to say that there is a considerable trend of opinion in lavor of motic drugs to considerable trend of opinion in lavor of motic drugs to considerable and the surgicial surgicial and produced administration which few individuals will or can submit to militate against their use with ut operative intervention. The juestion therefore is pertinent. What is the operation choices of a submit of the surgicial surg

The lack of such building results from tridec tomy in this type of plau once as in the inflam matory type mut not be taken to mean that iridectom of no a ail Hallauer's figures. showing 80 5 per ent 1th tension reduced to normal and it per ent if recurrences disprove such an idea Butler and I am record or cares of thronic glauconia with 70 per cent showing normal tension after indectomy and 87 per cent showing normal tensy a atter trephining. These figures indicate the unsiderable degree of effectiveness of indectomy and the greater value of a cystool icatrix Rochon-Du ignaud (44) states that about 70 per 'ent of trephine cases in simple giancome and chronic glaucoma with inflammatory intermissions are successful records 23 successful cases in 20 operated upon by Holth's punch method which be preferred to all others in 1900 Moray and Fournere (45) considered Holth's the method of choice and Elliot's next. The value of statistics would be greater if more explicit terms than successful were used. It a evident that the past decade has writessed an important development in the surgery of chronic glaucoma. That a cystoid cicatrix secu es drainage of ocular fluida sufficient to keep intra-ocular tension within safe limits. and does this more effectively than iridectomy in this variety of glaucoma is now an established fact. Which of the numerous procedures deargued to make such a filtering wound is to be preferred may not be stated with such positive-

Elliot believes his operation possesses very

distinct advantages in practically all cases of glaucoma Lagrange has emphasized the limita tions of his operation and indisted that it be not used as a substitute for indectomy in cases which are most suited to the latter. He reported \$4.4 per cent of successes in glaucoma implex Meller (46) has made a valuable report on a large series of cases comparing the Lagrange and Elliot procedures The Lagrange operation was performed ,80 times the Elliot trephining i 5 times Good results (by which he means ight preserved or if already lost the globe preserved with normal tention) followed in 60 per cent t the Lagrange operations and in , per cent of the trephined cases. The cases terminating badly were grouped together howing 8.4 per cent in the Lagrange operations and ... per cent in the Elliot. Meller was impressed with the com plications of the Lagrange method and con cluded that the maller scleral opening far for ward in Elliot's method i a distinct advantage He found the accompanying indectomy an im portant defense against prolapse He is opti mi tic about these operations for all cases in which indectomy is not emphatically indicated this includes absolute glaucoma secondary glau coma and buphthalmos. He credits Lagrange with having paved the way for the safer Elli t procedure Late infection occurred in i cent of the Lagrange cases and in 1 , per cent of the Elliot cases. The fact deserves mention supplementin" Meller's report that the Holth punch forceps operation eliminates the chief objections to the Lagrange method with the exception of the necessity of entering a narrow anterior chamber with a kmile (which the trephine avoids) and has been used with great success by some operators Reber (4) feels distinctly more hoperul since the introduction of the Elliot operation. He ecured improvement of vision in 13 of 6 cases after this operation some vi ion in eves which were blind when operated upon in cases and cessation of pain in 6 eves with absolute glaucoma

The choice of some one of these procedures for securing a cystod carative is a matter of individual preference on the part of the operator. Whether the incarceration of ins in the wound is an advantage over an ins-free circuity is a question which time must answer. Elliot's Lagrangee's Borthen's and Holth's two operation, are just now enjoying much popularity. That possibilities exist of a high degree of development of technique in these procedures is indicated by the fact that the chief objection to the existod circuits.

late intection of the wound seem in t to be met with by the originatirs of the peratrin, while other urgeons are encountered a himilihap

The question of intects n through the thin conjunctival covering if the sel ral pening i a serious one. While intait in a fixa a an effective barrier again t nat is r in m at is entirely possible that light traun a may at any time cause a minute brak nith buling in iun tiva which i e n tantly set a ain r by the lid. The nrt enthuirm rited ly th excell nt result to the viril unperation in glauc ma implex wa i i le al y lan iene l by acasonal refer to the interest Lp to January 1914 thirteen 1se ver recried Gitt rd at his recent the at north Numerou are have me nill it the literature important observation bein made by hur Kuhnt Av 1 l 4 and ther Paul had liected 1 print May 1 14 me ark in have been It aland a these peration in account tith fear flate interior The metal never what been extracted by T Harris n Butler (r wh c n lu le an article entitled. The Tracely 18 let 1 my with the Late injection is a peril which hangs like the wirl i Damiel ver every eye which ps seese a filtering of atrix of any type however Hi i ht ase are divided into three clases it a ute cases enling in uveitis and panoj hthalmiti, neces itating the removal case of severe and x valid, which destrive the light 31 cases of mild intis and local inflammation around the aperture which recover. On the other hand Elliot calls attention to the fact that cases of infection much be judged with regard to the ratio they bear to the total number of cases treplaned of which some oo had been recorded up to October 1914 makes the following observation. The condition tor which we trephine is not one in which the patient can choose whether he will be operated upon or not He has his back to the wall and we are tighting for his sight. Risks are then justinable which would not be worth taking for an operation for co-metic purposes

It is impossible to make a generally acceptable tatement in regard to late infections. There is no uniformity in expense as yet justifying a mail word on the subject. Certainly we cannot be as sanguine in regard to glaucoma implex as the earlier reports on the new operations seemed to warrant. Yet we cannot fairly offer wholesale condemnation of operations which produce excellent results in a difficult type of divease to

treat, just because a small percentage of the cases suffer from injection at the site of the wound in after months or years. Glaucoma simplex will for the present be combated by means of one of the operations which secure a cystoid cicatrix in the hands of surgeons who are convinced that more cases can be cured by these procedures, after deducting those which later become infected, than can possibly be cured by any other means. This type of glaucoma will not be at tacked by means of these procedures in the hands of other surgeons whose fear of late infections leads them to preter fridectomy or the more temporary expedients coupled with massage and miotics. When cystoid cicatrices are made, pa tients will be warned that an element of danger exists and precautions taken by frequent irrigation of the confunctival sac and perfodic visits to the onhthalmologust. It seems today that the prognosis of glaucoma simplex is distinctly better as a result of the scieral operations available than it was ten years ago For a careful ex position of this subject by a master of ophthalmic surgery the reader should consult the textbook of the late Dr Charles H Beard (52)

There remain several other types of glaucoma concerning which a few words are necessary

Hemorrhagic glancome does not yield to irl dectomy or to the newer scleral operations. There is great danger of destructive hamorrhage following these methods. Anterior scierotomy is safer as a temporary measure, and may be repeated. Heine's cyclodislysis may be made following posterior scierotomy. Unfortunately enucleation is the frequent end result of all forms of treatment

Absolute glaucema the condition of stony hardness of the globe and extreme pain, may be rendered comfortable at times by posterior sclerotomy and by trephlning. These procedures may delay or prevent enucleation.

Secondary elauceme demands the vigorous treatment of the primary condition. porarily the transient punctures of the scient are utilized Heine s cyclodialysus promuses more prolonged effect.

Bushindmes is notoriously resistant to all treatment. Anterior scientiony may be done repeatedly Fage (53) reports 14 cases in which this operation gave normal tension and 5 cases in which the growth of the eyeball was checked. Zentmayer (54) has compiled the experiences of a number of surgeons by means of a exestionneire and concludes that some form of sciencetomy is the best procedure of these the Elbot trephining

seems to be preferred. Heine a cyclodialysis bas also given some good results.

A discussion of the surgery of glancoma at the present tim must lack finality. The past decade has been fruitful of many ingenious attempts to solve the difficult problem of saving vision in a peculiarly baffling disease. Time will sift these operations selecting the more effective and less dangerous ones for use chiefly in glaucoma simplex Just now it is more important to study the problem with an open mind than to esponse the cause of any one operator or operation.

GENERAL SURGERY

SURGICAL TECHNIQUE

OPERATIVE SURGERY AND TECHNIQUE

Shaw II A. Infolding and Peritonealizing Stitch with Application of the Same to Broad Lies ment and Gall-Bladder Surg 6 am & Oksi 0 6 XXII. 73

Shaw condemns the technique of cholecystostomy as advocated by Williams in SURDERY GYNECOLOG AND OBSTRUCE, January 10 6 H applies what he calls an infolding and perstoneslisting stitch. The advantages claimed for this stitch as summed up by the author are

Convervation of tissue. In cholecystostomy we are endeavoring to preserve the gall-bladder od rest re its function. By this method we certa niv do not greatly diminish the capacity of the rall bladder

There is no dead space.

1. It produces perfect invention in a simple, rapid. and efficient manner

4. It renders easy the accurat insertion of the drain to just the correct depth. The tack sutur in the drain serves the doubl purpose of fixing it a cits and assisting in preventing eversion of the cut

edge. By cutting loop and pulling and tying from both directions, it produces smoother and easier traction and a more symmetrical and tighter purse atring around the drain.

The practice of suturing the drain to the abd minal wall is cond mucd for the following reasons

It does not allow for the natural mobility of the liver which assumes a somewhat different posttion, according to postu e.

The liver to a certain extent participates in Therefore t m unwise the respiratory excursion to fix the drain t the moving parts i. e the abdominal wall and liver

3 Tb bdominal stitch is applied after the wound is closed and is almost sure to draw the gall bladder upward or force it into an untoward positlon.

Sh w th n proceeds to pply this stitch to the technique of salpingo-oophorectomy claiming that th special indications of (r) bloodless removal of the mass, (s) closure of the gaping defect in the broad ligament, and (3) peritonealization of denuded areas are all accompanied with rapidity and case by this method. H illust ates this procedure by anatomicoschem tie dagrams.

Aruna, G. B. Th. Introdermic Suture: Its Techniq e La sutura intradernika su technica) Sena mend 9 6 xxiii 6 5

The utbor discusses th alue of intradermic utures from the owners, standpol t in leaving the mallest possible amount facer on the skin. Chas-⊾ gna troduced thi uture method in 1851 unthe name al ceilula or aubeutaneous autu ea, and in Nio Kental Franks, an English surgeon, rays d them unde the title of subcuticular su : 03 h h although not substantially different from Chassa gna yet coming in the period of antiseptic proxedu es lumed m e particular atten Si c then the method has been popularized by I oza and others

٩nc mu t description of th technique of intradermi sut re es not given as far as Arana can disco er i om n extensiv search in a y published work or so, ety report it describes this technique in the gre test detail and illustrates the various term of the method so as to make them clearly in telligible. H thinks that this intradermal anture is the nly one which is capable f giving a slimple linea cicatrix

With the technique used he considers that longit dinal at t hes are best. Horsehal is used with a Hagedorn needl It is necessary t obtain a practical acquaintanc with the details of the technique as p acticed in th operating room. The time consumed is no more than that required for ordinary out ring Prior t the intradermic suture a contin ous suture of the cellular fatty tissues is made which will avoid subsequent harmatometa

Intradermic suture is indicated in all cases where it is desirable to hid a cicatrix and it is formally indicated in interventi m in th face neck, and breast and other visible parts especially in women. It is employed exclusively in operations which heal by first inte tion. The method is contra-indicated in septic operations or in cases in which the general stat of the patient does not permit f cosmetic considerations. In some cases there may occur as an exceptional result an exuberant cleatrix where the skin is overirutable or very fine, ad in such

cases it is necessary to re-operate as the relanse of such an exuberant cicatrice is fatal

II I BREVEIN

Shorten J A.: Continuous Irrigation of Wounds in the Field India M Ga 1016 Li

The author has devised an invenious apparatus for continuous arresation in the field. An empty kerosene tin is placed on a suitable stand and rubber tubing used to siphon the fluid from the can to th wound By means of adhesive plaster the catheter at the end of the tube is fastened at the desired depth in the wound. The patient's bed is then inclined and the patient turned on his side so as to drain the irrigating fluid and discharges into a rubber sheet draining into a bucket J H Skilles

Black, C. E.: Some Experiments with Rubber Glores. Su g Gynce & Obst 1010 xx11

This paper consists of a series of observations on the sense of touch, in the use of rubber gloves author selected six high school students at the Illi note State School for the Blind - 3 boys and 3 girls and had them read a given amount of text (100 words of unfamiliar text) with various weights of gloves and with gloves put on dry wet and with the hands oiled gloves which were well fitted and gloves which were loosely and poorly fitted. These various observations were compared with the sense of touch with the bare angers under the same c n ditions The following are the author's conclu-

The use of medium weight rubber gloves re quires the blind to use an average of 22 econds more in reading 100 words of Braille than with the bare fingers namely 48 seconds with the bare nn gers and o seconds with medium weight gloves Or in other words there is a loss of nearly so per cent in the sense of touch judging from the result of this experiment

2 The tactile sense is materially improved by putting on wet instead of dry gloves the differen e being an average of avereconds or a little less than to per cent Gloves put on with oil on the hands give a slight improvement over dry gloves namely 68 seconds as against o seconds

3. The tactile sense diminishes in direct propor tion to the thickness of the gloves as shown in our hist series of observations where thin glo res showed an average of I seconds thick gloves showed an average of 106 seconds as against an average of 48 seconds with the bare ingers

4. I marked improvement in the tactile sense is brought about by the use of carefully fitted glo es as shown in the second series where by are in it ting the average was reduced from o seconds to 66 secon is

5 1s a final conclusion we may say that the final result of the experiment is that gloves put on vet give the most favorable opportunity for ever using the sense of touch and gloves put on dry give the least favorable

plete rures

During the past few years many sporadic attempts have been made to stan lardize the care of the surgi cal patient both before and after operation. attempts have nearly always failed to elicit any enthus m either because the collaborator had tried to introduce some theoretical methods or because surgeons as a class, lay m r emphasis upon operative technique then upon details of pre and post-operative care. This lack of detail is probably the cause of many poor surgical results.

In this paper the author covien the entire ground of routine per and post-operative care in pelvic and abdominal operations upon women. It has been this practice, during the past five vezers to gradually work up a printed order blank which is left on the patient's other than the hoppital. Enough blank patient's chart in the hoppital Enough blank patient's chart in the region of the product arrivations are left on this condition of the product of the pr

ASSPTIC AND ANTISKPTIC SURGERY

Maurel: The Method of Action of Certain Antheptics and of Procedures for the Determination of Their Therapoutic Value (Du mode d action

of Their Therapoutic Value (Du mode d'action de certains antiéptiques et des procidés dentinés à porécier leur valeur thérapoutique) Beil Acad. de méd., Par 9 6 l'exv 48

M urel calls attention to the results of the experiments, published 5 years ago, on the leucocytes of the blood, which in the light of recent researches on antisepties have be believes, a new significance. The results summarized are as foll

r That the pathogenic power of microbes ppears to depend on two series of products, one series due to their surroundings and the other to their own

substance,

The product due to their substance has

strong elective action on the leucocyte It is leucocyticidal.

 According to Maurel's researches certain physical and chemical agents can diminish the action of this leucocytickial power considerably and help the leucocyt 1 resist.

 The diminution of the leucocyticidal power of a microbe can be very marked without its reproductive power being sensibly modified.

5. Iodoform, fodine solutions, and me cury bibliorid solutions can he e a very marked effect on the leucocyticidal powe of microbes, or at least on certain ones.

6 It may be concluded, therefore that in order that an antiseptic agent may have useful effect on the organism invaded by a microbe it is not necessary that the autiseptic kill the microbe or even that it hinder its reproduction. It is suffici at if it diminishes its leucocyticidal power sufficiently that the leucocyte can triumph. W.A. Barroum

Ouena, E. The Manufacture of Catgut (La fabrication d catgut) Bull Acad do mtd Par p 6 lexy 530.

The question of categot is such an important one in surgery that the Paris Academy of Medicine appointed a special commission 1 consider and report on the condition of its preparation.

Since Pasteur's discoveries objections have been made to catgut as a suture material and although various attempts at sterilization have been made laboratory experiments has e demonstrated that phenic cid chromi acid, and aubilimate has failed t c mpletely territor categut and some sur geons including Koch r and Terrier renounced its

Hering H E. von Sudden Death in Chloroform Narcosis (Der plotzliche Tod in der Chlorof rm narkose) If enchen med II ck 10,16 km 521

For the past four years Hering has called att in ton to his own findings from animal experiment that sudden death in narcosis particularly chloroform narcosis is due to heart flutter. A review for the literature of the past twenty five years show

that this is fairly well established

Cats and dogs may dle suddenly in the beginning of chloroform narcosis and the sudden death in such cases is due to over excitation of the cardiac chain bers. In man unquestionably the same thing I true whenever at the beginning of narcosis the heart action is no longer evident and even if respiration has not stopped. In such sudden deaths in man excitation plays its part

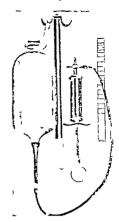

Since extrasystole can be placed in the same cate gory of heart irregularities as heart flutter and may even change into it on the grounds of animal experimentation chloroform should not be administered to patients with extrasystole eren when such extrasystole is sporadic only. Moreover since the existence of latent extrasystole can easily be deter

mined chloroform narcosis should be avoided

Bartlett W. A Method of Facilitating Infiltration Amesthesia is Surg Phil 9 6 1810, 678.

In order to avoid loss of time and energy to the operator as well as discomfort to the patient due to the reintroduction of the needle, a number of forms of apparatus have been devised to facilitate the administration of local infiltration anaesthesia. accompanying out represents a method which Bart lett has found very efficient and which is very simple While original with him, a similar apparatus was described by Braun in the second edition of his book After the usual intradermal injection with a fine hypodermic needle a 9-cm needle is introduced and a field 18 cm. in diameter can be infiltrated without withdrawing the needle. The graduated container I is filled with 500 to 1000 ccm of a one half per cent solution of novocame to which has been added 1 ccm, of adrenalin 1 1000 for every 200 ccm, of novocaine By means of the two-way cock C the 10-ccm metal syringe B can be emptied and tilled as rapidly as the piston can be forced in and out. Leavitt M A Rectal Ancesthesia V F 3 Ga 19 6 li 248

The indications for rectal anastholia are operations around the head inc. k. and chest where the element of fear is in evidence.

The method of procedure is as foll s The rec tum is prepared by the administration of a cathartic the evening bef re follo ed by en mata and sup positories of chloretone to aniesthetize the rectal mucosa. Twenty minutes after the insertion of the chloretone morphine and atropine are given hypodermatically and twenty minutes later a mixture of oil and ether is introduced in the proportion of per cent of ether and 50 to per ent of so to One ounce of the mixture is given for every twenty pounds of body weight not to exceed eight ounces through a rectal tube at the rate of one ounce a minute In from 10 to 55 minutes the patient The length of the anasthesia varies goes to sleep from two and a half to three hours but it may be shortened or lightened by withdrawal of the mixture After operation the bowels through a rectal tube are massaged and cold water irrigations given to remove the oil and ether. Intravenous injections of normal saline solution may be given if the anses thesia is too deep

In only one case was complete failure expenenced in the same individual twice. This was thought to be due to resistance to any form of anaesthesia. No untoward results have occurred.

HEAD

Morestin II: Very Extensive Shell Wound of the Face Gradual Reduction of the Emuing De formity by Successive Extirpation of the Cica trix (Plale très âtendos de la face par étiat d'obus reduction graduelle de la deformué consécutive par vilipations occessives de la cicative) B li el min Sec. d chir de Par 0 6 xin, cos

In this article illustrated by photographs which show the very excellent results obtained in a piastic operation for extensive shell wound of the face Morestin calls special attention to the benefits of successive interventions, reducing bit by bit the extent of the electrized surface and the mass of sclerom tissues. His knowledge of this gradual method of reduction is based on hundreds of cases of cicatrices and mutilations of the face in his special service. The method is simple as regards manipulations, requires patience and time but gives excellent results, and the author thinks it should play an important part in modern plastic surgery. The method is described in detail.

W A. BECHNAN

Exe F Some Surgical Procedures in Gunshot Fractures of th Mandible. Preciouser Load. Q 6, xcvl, 447 The author tells of his experience while in charge of the surgical side of a military hospital of 150 beds

for eighteen months. In many cases the disabilities were present prior to cullstment, but many were accentuated by the unaccustomed physical strain of a soldier s life.

Seventy-one cases of inguinal hernia were operated upon, the Bassini method being used in all except

three cases.

Two cases of femoral hernis were also operated upon, Poupart's ligament being stitched to the pectineal fascia. The after-treatment consisted of twenty-one complet days rest in bed, and the nationt was not allowed to resume active duties until three months after the operation.

Sixty-three cases were admitted for operation for varicocole. The high operation over the external tine was done in each case with a vertical incision. These men were kept in hed fourteen days and were given a subsequent furlough of twenty-right days. Ten cases of hydrocele were operated upon.

Forty cases of varicose veins were treated surgi

Thirty four cases of malformation and malposi tion of the little too were operated upon, amoutation of the toe being carried out through the metatarso-

phalangeal joint. Twenth-one cases wer operated upon for ham

mer-toe by removal of the toe.

Four cases were operated upon for hallox valgua and rigidus excision of the head of the first meta

turns was performed in each case. In all but one case there was little or no improvement Thenty-one cases suffering from ingrowing toe

nall were admitted for operation. The almulest method and one which gave very sathfactory results was to remove the hole of the nail and scrape the nail-benring aren under general angathesia.

Twenty three cases of hemorrhoids were sublected t oneration, the auture method being preferred

I enty four circumous one were performed for nhimora naranhimova

Twenty for tunnil operations were performed,

somet mes thath remo all of adentishin ases of internal decaragement of the kneejoint are open ted upon by resection of the internal semiluna cartiloge

Lour ages of undescended tests were operated ur wally contrat

Fight cases of histula in ano were subjected to operat ve treatm at

F e me with known to were operated upon under lor I apesthesia

Thirty cases of a use appendicitis were admitted. of which twenty four were operated upon. There was one death from general peritonitis from per foration of the appendix

One case of outle media was admitted which terminated fatally following a temperosphenoidal abacces

One case of empyema following pneumonia was operated upon with satisfactory results

I IL SEILER.

Buldwin, M. Payno, J. L., Hayes, G. B. and others Discussion on Wor Injuries of the Jaw and Face Proc. Rey. Sec. Mod. 9, 6, v. Odontol Sect.

BALDWIN opens the discussion by describing the term, war injuries of the laws, and the effect of

impacts from pr lectiles on the law

Prequently the bone is not only fractured but communited, causing deviation of these fragments. further complicated by the contraction facar tissue and the formation of dhesions if the jaw be im properly treated, or not treated at all. Facial deformities result and the patient a life is made miserable by dribbling f sallva, obstruction of breathing, and many other annoyances. To correct these troubles, apparatus must be used in the mouth.

hich brings the work inevitably within the aphere of the dental surgeon or stomatologist. Baldwin visited Parls and Lyons, and found in each of these cities admirable organization of the law treat ment, and usually a dental surgeon at the head of each establishment. At Lyons, he found under Dr A. Pont, 830 jaw cases assembled in six large homitals. Early in the war the lack of stomatologic

cal service was shown by the number of bad results in these cases. In England, there exists at this time but one military hospital especially set aside for law cases Baldwin believes that it would be well to have such a special hospital in the district of each command in the United Kingdom, and states that the dental and stomatological arrangements of the British army bave always suffered from the lack of an experienced officer on the staff of the director general

Payne relating his personal experience stated that he has treated 22 patients and in addition he vasited France in August and December 1915 where he saw large numbers of soldiers suffering from every description of law injuries, under trent The chief trouble he thinks is nearly al ways with the mandible which is recognized as being the most used bone in the body It is more hable to serious damage in consequence of its exposed position its loose attachment to the skull and the action of powerful muscles and the displace ments also tend to be relatively greater than in other bones of the body The mere use of bandages and other external appliances seldom avails to correct this deformity He suggests the division of these cases into the six following types

I Fractures of the mandible without displace

ment of the line of occlusion.

2 Single fracture of the mandible with lateral displacement 3 Single fracture of the mandible with vertical

dusplacement 4. Two or more fractures of the mandible with

loss of substance

5 Gunshot wounds of the maxillar

Fractures involving loss of the anterior portion of the mandible or the maxillee or the whole of one side together with the soft tassue adjacent

These types are fully described and numerous illustrative cases cited. In answer to the question At what period after the injury should the aid of

the dental surgeon be called in? he answers I should emphatically say that it should be done as soon as possible after the wound has been inflicted and I believe that there should be co-operation between the general surgeon and the dental surgeon the dental surgeon beginning his work immediately after the patient has recovered from the condition of Efficient dramage is the first essential principle of treatment. Skiagrams should be taken at the commencement during and at the conclusion of the treatment Teeth should be freed from tartar blood and food. Carrous teeth should be temporarily filled septic roots and teeth should be extracted as soon as possible and any tooth that is situated in the line of fracture usually has to be sacrificed or union may be delayed application of a splint should follow as soon as it can be borne by the patient often the temporary appliance may be replaced by a permanent splint when conditions look more favorable In displace ments of the maxillæ support may be obtained by simple bandages or by means of suit il le at plannes After sensis has been controlled the next important step in the treatment is to restore what may remain of the masticatory apparatus by bringing by k the fragments of bone into a positi n v hi h permits of normal oc lusion. The treatment my be livided into the four following stages

- 1 Reduction of di pla ement 11 ny frigments Retention of these tragments in the positi n
- which allo s of normal exclusion 3. Reduction of cicarnetal contraction, the ris
- toration of mu ular equilibrium and the rim uld ing of the facial ontour 4 Fitting of a permanent pristh to applica-
- the impler the better so ling a it is lin n left i

The ain of prestheti treatment half be (1) to prect the d formity and for it reflecte the to the position of normal ocluring to ream the fragment in the position urtil uni n has oc urr 1 (3) lat r som f rm of 1 ntur ix have to be fitted to make good the gar. I it by lost bone and teeth and to restore the functional a tivity of the jaws. The idea that an interdental plint at an early stage will tend to promote sepail his believes to be entirely erroneous. During the third tage of the treatment frequent massage both manual and electrical by competent nurses should be a lopted to restore muscular equilibrium, and care should be taken to guard against cicatri ial contraction

HAYES states that no pathological problems or conditions have been met with in this work the difficulties encountered being due to the variety and complexity of conditions presented which d mand the most areful consideration. The principal treatment in these cases he believes falls upon the dental surgeon and the ultimate success depends upon the building up and restoring of the jaws as a skeleton or framework upon which the final plastic operation is performed. Much has been done but much remains to be done to supplement the special centers already created for this work in France There should be dental surgeons at the front to give first aid to these cases and to decide what re maining fragments of jaws and teeth shall be saved and what removed. There are many ques tions involving the treatment of these wounds now undergoing renewed and general study

HOTE also ventures the opinion that in all jaw cases combined with extensive destruction of sur rounding tissue the general surgeon should call the dental surgeon into consultation. He is in favor of simple rubber splints in most cases with the exception of those few in which the steady maintenance of fragments is indicated, and he objects altogether to maxillar, wiring as this creates a risk of ankylosis being set up If pressure from the outside is necessary he employs linen bandages or special chin-cups of rubber or metal with hoops fastened together from the attachment of elastic bands that will allow pressur in the direction in dicated by the case. He believes that a good method of procuring hygens: I wound in the oral cavity is to suspend receptacle, fitted with a rubber tube and glass cannols, above the head of the petient if fill it with a light tepid solution of from 5 to ore cent iodies or chloride of softlum, and to wash out the cavity thoroughly from three to as times a day according to the septic condition present

COLYER follows with a brief description of the result of his experience in connectio with the Croy don Wa Hospital. There are one o two main points in connection with the treatment in this hospital of which he speaks. As soon as the patient is dudited to the hospital, a peroxide mouth wash is given every two or three hours, and a 2 per cent solution of iodine is applied once every day Skia grams are bisined and short notes made the pa tient is then taken to the operating theater and given a general anaesthetic, usually chlorof rm attempts are made to reduce the various fract res Sentic root are emoved as well as the teeth in either side of the fracture. This is rule throughout the hospital. The next step con sist of the adaptation of splints, the fixation of which is generally left for two or three days or until ther is a certainty that all sources of sepas have been removed. When the patient is practically convalescent and the fracture is completely healed a etention splint is inserted also before going back to the front these soldiers ar put through a dietetic course. Before they leave the bospital, they are changed from a liquid diet to a minced one then to boiled diet, and lastly to roust diet

Colver believes that the most importa t displacements in the treatment of law cases are those that occur when there is fracture in the region of the last molar tooth very often there is involved loss of these to the extent of one-half to three-quarters of The solints he uses re very simple one t which he refers especially is known as the skull and mandible splint, consisting of a metallic splint moulded to the outside of the mandible in a knitted kullcap. Ununited fractures are usually due to the presence of a foreign body between the frag ments, and secondly t a lack of rest the foreign body usually being a tooth. Sinuses in connection with fractures of the law re, in majority of cases, due to aeptic teeth. Scar these is cut away freely from the law nd forcible stretching of the soft tissue by means of plugs of vulcanite is adopted. Stiff law in which the scars have to be stretched

Stip jaw in which the scars have to be stretched is treated by using continuous stretching over a definite period. He has done bone-grafting in two cases, both successfully

Six Fernaura Eve helieves that the ideal method of bridging over gaps in the mandible is transplantation of bone. This operation is rendered very much easier if splints are firmly commented to the technacross the gap. He has transplanted a portion of the eleventh int. He has not as yet seen a case in which plating in gumbot fractures of the mandible secreted advisable.

HERRE states that the treatment may be divided

int tw main st get [] the correction of deplacement put support of fragments while the healing of soft them. In the fitting I come protected capazitus for the replacing I lost parts esto atom of the function of masticat possibly also of speeches and reduct not definition from the fitting I consibly also of speeches and reduct not definition. The interval between these () results also devoted by the patient to the air citching of the six disaste and the massage of a v cit rough bands that may have formed dring the healing I the soft tissue. He believes the post of the tenth of the six disastent with the six patient of design and applied in manner which will avoid the damming of discharges.

MI HAVE Y r fers only to the methods dealing a th musung portions of the mandible where large or malle nortion of the 10th have been destroyed. leag gir ts out uity Where large por tons [bon muss a artificial restoration, be bel s the only ourse possible in the majority of instruces wh a portion extending one-half st three-must raid an have musaing he believes th tossecus unu n n ll t ke plac in the great ma ionts of uses. If loes not believe in the old meth od of bringing th f t red ends together by wiring them lthough h lives that t requires a longer period 1.1 t obtai a firm bony union across the gap th t dies ben the ads of the fragments Laut re in

The first of the f

u n tim spinninged dent res can be inserted with reasonable prospect of success. If has also de supred a temporary cap spit t which is uncernented, has the front cut wy is easily removable being light red t three or four teeth, round loops on the lingual side and ound vertical wires on the buccal side.

BEDOWN ways that his experience does not lead him to subscribe to the views of Colyer that the chief thing to seek is bony unon even if there should result some lack of normal occlusion. In regard to apparatus, he is in favor of removable rather than fixed spillar.

Cour also dissents I om the views held by Colyer on the question of occinion verms unlon and beileves, as does Hayes, that the presence or absence of a single took on a fractured portion may suffice to change the method of treatment entirely and further the believes that conservation of one or two particular teeth will render relatively easy what would other wise be a task bees with difficulties. So strongly is be convinced of this, that be has had root treatment carried out on the operating table. He believes, most emphatically that early reduction and retention of lengments in jaw fujuries are effectual means of combatting sepsis and add maternally to the comfort and well-being of the patient. He also thinks that the dental surgeon should be a skilled technician that he should be willing to make his services subserve the immediate and anticipate the ultimate requirements of the surgeon and he believes that the surgeon should have a working knowledge of the range and extent of the dental surgeon's possibilities and that he should know and make known his requirements

BESSETT believes that in all cases of surgical work on the jaw care should be taken to preserve every tooth that is taken out so that, in peace times they

may be examined carefully

JAMES has found that where there is contraction of scar tissue pressure can be obtained from a length of rubber tubing introduced into the mouth in such a manner as to bring pressure upon the contracted tussue gullet thin tubing is used at first and the heavier rubber introduced later. Pressure is obtained by an arrangement of the tube in a U form and it may be increased by tying the two free ends together to form an oval.

Prince agrees with Payne and emphasizes the four points with which the latter concludes the regrets that the authorities have allowed these cases to go six or eight months before referring them

to the dental surgeon

TURNER finds that Dekin s solution is extremely useful in these cases of sepsis. He agrees with the other speakers in the use of cemented splints, especially where there is a possibility of having to remove them in order to extract a root. Regarding the loss of bone he agrees with Mummery. He thinks that all metals used in bone repair are apt to work loose subsequently. Where the cicatira is once stretched a return may be prevented by the extertion of a small amount of force applied daily

CARTER believes that wire suturing of the Jaw causes fixation at once and is followed quickly by osseous union. He is in favor of silver plated copper wire (No 10-BWG), and a special key for twisting it up as well as a fixible needle for returning the wire The drill must not be revolved too rapidly or advance too quickly or necrosis will be caused by heating A small rubber tube to protect the lips is put over the twisted ends of the wire before being turned down or a thin strip of rubber dam may be wound round them and the two ends tied.

EMIL CROSTEINER

Rico I: Calculus of Wharton a Duct (Calculos del canal de Wharton) Rep d med y c Bogota, 9 6 vil, 343.

Calculus of Wharton's duct is of relatively rare occurrence. The author reports a case in a man of 50. Thurty years previous he had had acute pain in the left submaxillary gland followed by inflammation. Recently the pain reappeared in this region accompanied by fever etc followed by genuine salivary cohe and abundant discharge of saliva and pus.

By palpation a bard mass va Ikated in the direction of Whartons dut a nil th diagnosis of a calculus was verified by passing a wind. The patient would not permit ain risin it to be made Later on the call ulus peri rated the mucous lining and appeared in the mouth The vin pit ms rapidly disappeared.

W. I BEL NO.

Guibé Crantal Wounds in War Surgery C n d r at ns u 1 s plan lu hir d guerre) P s m d 10 p 5

In infect months Guilk has observed 3 rainal injuries of which 23 have been trephined. In the other 14 cases intervent in was used as They all died within 12 hours of their arrival.

As rigards the e-olutin of such injuries Gubé emphasizes the frequenty of crebral herma after intrention for penetrating wounds with Jura mater injury also the frequency of encephalitis and the rarity of meningits.

Non penetrating wounds in general heat penetrating wounds on the contrary are almost always fatal. Frontal r gion injuries are generally more benign than panetal.

Early intervention in necessary. It there is no functional trouble and no evidence of a lesion of the dura mater it is better to abstain from opening it. To prevent cer brail herma recourse should be had to repeated lumbar punctures but it is even better to make an early and sufficiently large treplination.

W. A. BERNEN

Schmidt P Pneumococcic and Meningococcic
Meningitis After Fracture of Base of Skuli
(Pneumokokken und meningokokke Meningitis
na h Schaed Ibasisfraktur) Deul ke med
Il k izch 9 6 Mil 14

Schmidt reports an interesting case of meninguiswith double infection by pneumosco: 1 and meningococi. The patient a workman, had suffered a fracture of the base of the skull and was removed to the hospital seven days afterward. He died the next day. Bacteriologic examination of the spinal fluid made on the date of his entrance to the hos pital showed pneumococci and meningococci in approximately equal quantities. The blood examination showed only pneumococci.

Autopsy showed a fracture of the upper part of the sphenoid and ethnicid insure. The durn mater was not injured. Blood-clots and mucus were found in the sphenoidal sinus the nuccos of the superior nasal cavity was tumefied and inflamed. There was no inflammatory process in connection with the ethnicid and sphenoid. The lungs showed on both inferior lobes bronchopneumonic multiple food of three or four days formation.

That the infection of the meninges in this case was direct from the inflamed upper parts of the nasal cavity either through the ethnoid fissure or that of the sphenoid and therefore by the lymphatics and not by the blood seems to the author not to need demonstration. If the infection had been

through the blood it would be natural to expect that this would have shown the presence of meningococd as well as pneumococd W. A. Brimman

Kapoky J P Thyroid Tumors of Bones, with Special Reference to Non-malignant, Pulsating Tumors of the Skull Surg Gyace & Obs. 10 6 201, 670

The uthor reviews th literature on thyroid tem is found in bones and gives a brief resume of axes thus far eported. He describes in detail a case coming under his own observation. As a result of his tudy he concludes

That from the literature the majority of lovestigators conci de that primarily all in tastatitheroid tumors are histologically benign

2 That metastatic tumors could result from mall particles of thyroid these which have fou d their way int the circulatory apparatus 3. That in many cases of thyroid metastates ther

3 That in many cases of thyrold metastatu ther is no hyperthropy of the glands or apparent pathological condition

4. That the malignant character of some of these tumors is due to some secondary inflien possibly engendered by the thyroid cell a ting as a foct if continued irritation.

5 That the deposition of embryonic thyroid cells is tenable and may be the greatest factor in the production of thyroid metastases, but the growth of such cell outside of its direct environment is made possible by some peculiar systems: and tool as yet unknown.

Leopold 8.: Circumscribed Purulent Leptomenin gitts Du to Frontal Sinusitis. J 4m 11 4m a 5 livi. 616

Two cases are reported. These cases, as well as a study of the literature above that the ymptoms are frequently preceded by weeks or even months of nasal catarrh with frontal headache or they may occur after only a few days following in attack of influenza. Edema and discoloration of the eyelid, with tenderness over the orbit frequently precede the cerebral symptoms when desease of the wall of the sinus or orbit is present. Frontal headache is present in nearly all cases, though pain in the head is not limited to that region. The pulse and temperature are not characteristic. Rigidity of the neck and Kernig s sign, though noted in both th cases reported are not frequent symptoms. P ralytic aymptoms are noted usually in a later stage of the discuse. Irritability and restlessness, alternating with clouding of the sensorium, are sometimes the only meningitic symptoms present and death sometimes comes before the development of permittic symptoms. The pure meningith following frontal sinus disease is less frequent than brain abscess, but much more frequent than thromboohl bitis.

The explanation of this phenomenon depends on the route of infection which may be direct, through the intensifies or necrotic walls, or indirect, through the vene perforantes of the simus and orbit or through the lymphatics

It seems that in many cases the dora escapes involvement that incision is necessary in all cases in which absence of lesions on the surface is noted This holds true not only for the meningitic cases, but also for the bdural and frontal lobe abscesses. Enwaso I. Comput.

Hartmann, H. Cranial and Craniocerebral Wounds (Plaies on stones et crano-cérébrales). Bull. et m m Sac de las d'Par 0 6, letil, 1901.

Harimann a observations are based on 159 cases reported by different operators. Of the injuries for per cent were in the paraetotemporal region 5 per cent in the frontal region 15 per cent in the couplai region. In 15 cases there was a complete fracture of the skull a du 85 of these the dura mater was no loved.

The prognosis of cranual injuries by gunshot is grave and errors not only with the intensity but also ith the sit of th leafon, temporal selsons being the most were a parietal frontal and occipital follo ing in severity in the order named. The last go es oo per cent recovery W.A. BERECUL.

Villaret M d F ure-Bea lleu The Grave Accidents of Lat Appearance in Cenalocerebral Wounds of War (Le scid t grae a dapparition tardive hea its bleads d guerre cranic-cerebrau). Bull craries Sec. mid d hip de Par 9 6 xxxii 535

The authors give particulars of sy cases of cranial would not of a total of 250 which have presented grave accidents appearing several monito after the tra mas. These cases are classified under four heedings (1) late epitepsy () grave mental troubles (3) menungeal infection and aboress of the

brain (2) fair brain herma.

Mental troubles and late cerebral hernia are exceptional. The most frequent and important result,
are late repliesy and supportative menting-occepha
litis. Memingitis and supportative needing-occepha
noted inforce cases appearing from two to eight months
after the traumas. The study of these cases has
aboun the important part played by the pentit nee
of foreign bodies and metallic debris in the lesson.
In the case of lat epilepsy it is most interesting
from the point of view of the lapse of time after the
trauma. In one case this extended to thirteen
months but most often it oscillates between four
and ten months

Most of these cases have been trephined for the primitive injury

The peractical conclusions which the authors draw from their study of the cases are that in the cases of of men trephined or presenting traces of craniocerebral traumas, the future proposals must be reserved even in the absence of flagman symptoms of central nervous lessons. Systematic radiologic examination of the crani m should also ye be made il discover metallic debts or ossessous particles these are foci which provoke late grave results Such men should not be returned to the front but kept at duty in the rear under medical supervision W A BRENNAN

Sharpe, W: Observations on the Diagnosis and Treatment of Brain Injuries in Adults

Am. M Arr 1916 lvv1 1536 The author believes that the mortality of brain injunes in adults has heretofore been high (at to 68 per cent in all cases) because patients have been allowed to reach the dangerous stage of medullary compression. The signs and symptoms giving

warning of increased intracranial pressure and result ing medullary compression are carefully discussed and the importance and value of frequent observation regarding pulse optic discs intraspinal pres sure and the presence of blood as noted by lumbar puncture repeated if necessary are pointed out

In a series of recent brain injuries, chiefly fractures of the skull operation was performed on 70 with only 14 deaths. Operation in the presence of shock with a pulse rate of over 120 is absolutely contra indicated

While valuable for diagnosis lumbar puncture should not be used for the purpose of lowering high intracranial pressure for fear of medullary choking in the foramen magnum

I rays are of little importance in the treatment

of fractures of the skull

As regards late results of untreated fractures of the vault or base the author looked up a series of cases and found 67 per cent were still suffering from the effects of the injury

The common complaint was headache on exertion Other symptoms were vertigo irritability and epileptiform spells, the patients often being disqualitied for employment. Of these cases 4 per cent had had a pulse rate below 70 following in

The author believes the late results are due to an increase of intracranial pressure for a long period Treatment in the majority of cases with increased intracramal pressure should be early decompression all compressed fractures of the vault should be elevated or removed for fear of later complications I alliative treatment may assist in bringing about recovery in milder cases but the large proportion require operative relief of the increased intracrumal pressure due to hæmorrhage or to the increase in amount of cerebrospinal fluid sufficient to produce a wet ordematous, swollen brain

In post traumatic conditions due to long increase of intracranial pressure a large percentage can be improved by operation. The operation of choice in both selected acute and chronic cases of brain injury is subtemporal decompression. The author recommends a straight vertical incision from zygoma to parietal crest and longitudinal splitting of the fibers of the temporal muscle This gives better hæmostasis and union of the divided muscle. HORACE BIXMEY

Grev E. G Studies on the Localization of Cerebellar Tumors the Pointing Reaction and the Caloric Test 4 m J M 5 110 1 / 13

The records of at cases of at hellar and extra cerebellar tumor are discussed relative to the im portan e of the pointing rearrion (Barany) and of the calonic test

The situation of the gr withs in the 31 ages was as follows 3 in the vermi to in he hemisphere 5 involving the entire cerebellum 8 ccrebell pon tin and rextractrebellar

(rev concludes that the culors test has prived to be an important means of differentiating laby rinthine from intra ranial disease. Together with the pointing reacting this test has been jound of value in localizing consumscribed less us in the cerebellum

In most patients having tumors in the erebellopontin region new growths and in certain of those with tumors of one or the other hemist here the reactions were sufficiently characteristic to be of supplementary value in localizing the disease In other patients with intra or extra er bellar tumors the results wer often ambiguous at varian e with other physical findings and had great reliance been placed upon them would have led t erroneous con lusions

There are probably a number of factor responsi ble for an atypi ul rea tion in patients with erebellar tumors among which are (1) gr atly increased intra ranial pressure fue to internal hydrocephalus and (a) the diffuse nature of many of the tumors common to the cerebellum D. L. DESPARD

Livierato Spiro and Cosmettatos G F Tumora of the Hypothalamic Region of the Middle Brain ibui t mon dilla regione ipotalamica del rervell int rmedio) R forma med 0.6 \11.440

Tumors of the hypothalamus of the brain com prise those which develop in the mamillary hypophy sary and chiasmatic regions. Their development and the consequent compression not only provokes destruction of one of the regions mentioned but also of the nerves which traverse the base of the cranium in the neighborhood of the hypothalamic region and thus produce multiple cerebral phenom ena. The symptomatology varies according to the point primarily attacked and the more or less rapid progress of the tumor

The authors report in detail a case of psammoma of the hypothalamic in a woman of 37 In addition to general and nervous symptoms the patient showed marked special sensory symptoms was complete loss of smell on both sides also atrophy of the papilla of the optic nerve both left and right followed later by amblyopia of the left eye with persistent intense pain. A cerebral tumor was diagnosed and a trepanation done in the right tem poral region, but nothing of importance was discovered The woman died in coma six days after the operation The tumor wa demonstrated at autopsy

In reviewing the literature concerning the fre quency of tumous of the perithinsmate regin a the authors find that in the case of tumors developed in the memages, into which category their own case falls, only three anch cases have been reported. They state that the case reported by Heinrichsdorf and their own case coordinate aspecial category is that of pasamonata of the prechasmatic region, and that these two cases are the first reported up to the present time.

From the anatomocificial study of the and other cases the authors find that it monolateral involvement of the optic nerve first observed and accompanied by anosenia fixed the locati n of the tumor at the antenor angle of the histam. Thus anomina which is dut a destructive compression of the perforated anterior subat noe or of the of actory nerve has a great diagnostic value particularly when no other nerve besides the optic is involved. The compression or destruction causes degeneration of the nerves of Lancial which unit the peripheric and central offserory poratos.

The authors claim that circumhypophysars tumors may develop and attain great size without the hypophysis itself being clearly attacked or disturbed in its functions.

W. BEERSAN

Caster, M., and Cost S. Adenocarcinoma of the Cerebellium (Adenocarcinoma del rebello) Presis més Argent., 9 6, No. 30, 36

The author describes the case of man y rears old, who had been ill for its months with solent and continuous hesdaches, localized in the anterior part and right side of the bead. He rocunted sithout initial names and without the ingesti of food times, nauca was on intense as i intricer with his standing or walking, and he had manifestations of falling on the left side. The patient was constipated. Reflexes, police, Romberg, lungs, pupils, etc. were all normal. The urine and blood were negative. Lumbar puncture gave out liquid with normal tensi in said dowing drop by drop clear. Apolt a and albumin reactions present.

The patient ecrived biocyanid of mercury (or t o or cg) daily intravenously and 4 t 6 gm, of KI, daily. The symptoms diminished n intensity f r the first week From the fifteenth day however, the symptoms increased to uch an extent that the patient could not move from his bed his eyes were closed and he mouned contin ously The cephalalgia became so extrem that th patient would tak his head between his hands and scream in gony The headache was no longer frontal exclusively but occipital as well. The position he would assume in preference was right lateral decubitus and pain was evident upon muscu lar pressure. Bablaski sign was present on both sides. Deep and muscular sensations were present The pupils reacted well, but were found to be unequal. There was left facial parests in the region of the superior and inferior facial There was bradyla

lia and a depressed intellect. After another lumbar puncture which showed o tubercle bacilli n r positive Wassermann op per cent lymphocytes and per cent polyn cleans, the patient entered a

state of c ntinuous eventement and was unamenable t morphine treatment given in repeated doses. The symptoms or tinued unabased until a comatose onditi much and death occurred several hours thereafter or bout s months from the onset of the disease.

As t the diagnosis there were two possibilities a tumo of the right frontal lobe, with cerebellar symptoms du t counterpressure and erobellar tumor in the right hemisphere. An

tonsy f mished the following findings Dura tense and hyperemic cerebrum markedly congested. A macroscopic examination of the cerebellum show ed that the tire right lobe and the isthmus were of gelatinous consistency. The border or the poste no margin of the right bemisphere p esented a stratificat n of the circum lutions, much less than n the left thout an in of ement of the meninges. A horizont 1 incision was mad passing through the center of both cerebella bemispheres and comprising th median cerebellar pedundes, also the dentate nucleus. I teresting changes were observed. An enormous mass occupied the posteror third f the right hemisphere and from it flowed a substance of an ibumi ous consistency, f yellow pinkish color leaving behind series of cavities, f w in number and of various sizes. The mass was of a heterogenous aspect som parts compact others spongy some hard others soft of a mixed color th detinite borders i some parts and diffuse in others infiltr ting the nervous tissue in some parts, compressing and covering t entirely in others. Vasculanty rich Certain zones were easily enu cleated, while the greatest portion of the mass was infiltrated nd could not be deated. The anterior posterior diameter of the mass was 3 cm. transverse dismeter 4 cm vertical diameter 3 cm. The shape was more or less spherical Its antenor part was ot smooth. The cortical substance of the circum rolutions was not invaded it was found compressed and crushed but not attached to the tumor

A histology at dy of the t mor aboved it to be a tumor of carationnat us type with cylindrical cells, of the f m known as adenocarcinoms. The coplestic cells howed carteneoprolliferation. Apparently there was no relation of contiguity or continuity between the carcin ma and the fourth ventricle, whence epithelial pierus could have originated. The cylindrical type of the adenocarcinomic pieces are continued to the continued of the cylindrical type of the adenocarcinomic pieces.

matous cells have probably a direct or indirect relation t th ventricular ependyma

RAOUL L. VIORAN

RECK

Geist, G. A. Congenital Cysts and Fixtuin of the Neck. St. Peni II J 9 5, xviii, 57

The a thor insists that congenital cysts and fistule of the neck must be divided into twe groups,

according to the embryologic origin of each (1) me dian and (2) lateral cysts and fistulæ. He then takes up the subject of median cysts and fistulæ and gives the theories of their origin as outlined by the works

of Streckersen and His.

The views of Wenglowski as published in 1012 are quoted. The sile of the opening depends greatly upon the size of the cyst and upon the attachment of the cyst wall to the skin due to inflammatory processes. Cysts are usually irregular in shape projecting into the connective tissue and if ruptured the resultant fistula is tortuous making the passage of a probe difficult. Injection of colored or flavored liquids to determine d possible the communication with the foramen cacum is usually futile unless pathological rupture into the mouth has occurred.

A patient aged 21 years presented a subhyoid median, institutors opening Diagnosis was made after an injection of bismuth paste and \ ray Total extirpation of the walls of the cyst was per

tormed with good results.

Lateral fistule are classified as complete and in complete and the latter divided into incomplete internal and incomplete external fistular. The complete occurs in the young or is present at birth but the cyst formation occurs in later life. Fistular rarely bilateral the external openings are usually single. The secretion is a mucous find clear or turbid the amount varying from a few drops to an almost continuous flow.

The caliber of the canal is so small that the finest possed with difficulty or so large as to allow the passage of food particles from the pharynx Injection of fluid will establish a diagnosis of complete or incomplete fixtula. The diagnosis of lat eral cysts is not so easy as in the case of instula.

Gest believes there are two methods in the treat ment of cysts and fistule of the neck (1) injection of irritant drugs into the fistula or cyst (2) total extirpation of the cyst or fistula wall, the latter

being the better

Two cases are reported. One case was a guil of cight years who presented two small openings med way between the chin and the clavide over the sternocleidomastod muscle of the right side. The other was that of a woman of thurty years who pre sented a vertical scar two inches in length in the muddle of the border of the sternocleidomastod muscle, and in the lower end of the scar a small, pun point opening was present. Both were operated upon with good results. Exm. C. ROSITISELE.

Becoula: Results in Seventeen Cases of Neck Resection in the Secondary Feriod of Traumat ic Arthritis (Resultats de di sept cas d'execti n du coude dans la periode secondaire de l'arthrite traumatique) la desense de de d'a Par 1915 Ali, 803

Begonin points out that the enthusiasm of Lenche and other partisans for immediate or very early resection of the neck in cases of arthritis should be tempered and that the advice of Quenu should be followed who urges that there be further observations before oming to a definite conclusion in the matter

Begoun gives the results of r ases if resection of the neck in cases of arthritis caused by projectiles in which operations have been performed by different aurgeons and in which Begoun has had the opportunity of judging the end results which are quite deplorable. Of the 7 cases the neck is unbalanced in 15 and the forearm is in rt even after effort in the other two the arm is somewhat better but still the patients cannot raise anything to their mouth nor button their clothe.

Begoun thinks that the good results reported have occurred in the case of surgeons who were specially familiar with this resection and were able to devote sufficient time for personal supervision of the after treatment with his most unportant.

In the hands of the average urgeon he thinks the results will not be better than the perported and he is of the opinion that interference by resection in the secondary period will n t give as good results as would be obtained by allowing an ankylosis to be stabilished in good position. Large arthrot only incisions lavage of a genated water curret tage etc. should be the treatment which will either effect a recovery of lava can ankylosis.

HARTMANN QUENT and BROCA discussed the paper and the general opinions expressed seemed to favor Begouin's views with certain reservation

W A BRINNEY

Bell A J Prolonged Use of Tubes Following Diphtheria A ck Ped tric 19 6 x 61

The patient aged one year was suffering from larvingeal diphtheria with a history of having been sick about two weeks. The child was decidedly toxic temperature rog 2 pulse 130 or more and the respirations of the Chey ne Stokes type. There was marked retraction of the cheat wall upon inspiration. No membrane was visible upon the tonisls or phar yir. A dose of 20 000 units of antitoxin was injected into a vein and 5 000 into the thigh. The respiratory failure was due to the general toximia. On attempting intubation, the patient ceased to breathen and went into profound collapse. The pulse could not be felt nor the heart sounds heard and for several minutes the child appeared to be dead.

A low tracheotomy was done artificial respiration performed and stimulants given. The patient smally began to breathe, at first with only mechanical gasps due to the manupulations and then by the return of the pulse. After breathing began, sufficient all rentered the lungs, but a most distressing cough kept up for half an hour or so. This was immediately relieved by allowing two or three drops of a 2 per cent cocaine sulution to run down the tube. Steam inhalations and tent were used from the start. For several days rectal feeding was resorted to because of the tendency to choke. On the fifth day a very slight amount of air entered

through the laryns when the opening of the tube was closed. On the seventh day the tube was removed for fifteen minntes. Although some air entered through the normal passage nearly all the breathing was through the opening in the next.

On the finth day 20,000 units of antirozin was given on account of the large ordemat in welling of the fauces, which mechanically interfered with leeding. This condition improved the following day. Between the night and the twenty first day there was no charge in the tube situation. On the twenty-eighth day the child a temperature was nor mail for the first time. On the twenty-malt d y the patient a general condition was excellent. The finger was placed over the opening of the tube and a sodden pressure applied to the chest wall with the reach that the child uttered dust if cry and

coughed several times. This was successfully repeated every few minutes for half an bour. On the thirty first day the trachestomy tube was removed permanently and the child had no further difficulty in breathing through the larynx.

Without warming or physical signs to account for it w days later the child developed a subnormal temperature and typical Cheyno-Stokes breathing On the hitty-fifth day so coo units more of antitotin (making in all 65,000 milts) was given. At this time the threat cultures were still positive Aiter this further proprets was uninterrupted. There were no paratyses of any kind phonation than the condition of the harden beautiful and the condition of the harden been in the hospital for two months.

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Durante, L., and MacCarty W. C. Tuberculosis of the Breast, A. Sarg. Phila. 9 6 Juni 668

The thore have observed to cases of t berculoals of the b east. In 3 of them no primary focus was chincilly demonstrable in 3 no chincil tubercu lons lesson except the amiliary lymphatic involvement was demonstrable, in t there was an associated pleurecontal lesson and in 3 there were vidences

of pulmonary tuberculosis.

From review of the literature the foll was seem t be the important point in the disease

The period of greatest asceptibility is between the trientieth and fortieth years. A total of 80 cases have been eported.

Although there is no apparent relatin betteen the two diseases 7 cases have been reported in association with neoplastic processes.

3 Practically every case is secondary t primary focus elsewhere in the body although infection by way of abrasion in the skin is possible

Fig. Showing the line of facision. (Jennings.)

4 Most observers have considered the blood stream to be the most common route of infection, though in certain cases the organisms were apparent by carried re enerly from the neighbori g lymphatic

glands
5 A microscopic diagnosis is essential in practically all cases although other means a chast cultures, smears, and gumen-pig injections aboutd not be overlooked.

Lenormant, C. Some Observations Regarding the Removal of Projectiles by Thomcotomy (Quelques observations de projectiles 1 és par thoracotomie) Bull et mêm Soc de chi de Par 1916 lij, 57

The author reports 8 cases of removal of intra thoracte projectiles by thoracotomy and the particular point to which he draws attention is the advantage of large pleural opening. He thinks the procedure of choice is the resecution of a single rib for a distance of 10 or 12 cm. This can be done bloodlessly in a few minutes and without any ligature being necessary later.

It gives ample opportunity to palpate and examine the thoracic cavity to expose a pulmonary lobe if necessary to approach the mediastinum and to raise and incise the diaphragm.

After operation a few sutures of the soft parts of the intercostal spaces will hermetically close the thoracic breach.

The large opening of the pleura has never been the cause of any accidents in the author's practice. For a long time he insisted on the harmlessness of operatory pneumothorar, and he thinks that recent experience in intrathoracic surgery has continued this opinion. The fear of opening the pleura should be dismissed from the surgeon's mind. Under a rigorous asopais the operations can be done in the thorar just as in the abdomen.

The majority of Lenormant's patients have had a total pneumothorax. None has shown the least respiratory or circulatory incident. If there should be some irregularity of respiratory movements on the entrance of the air traction of the lung will retore order.

In this procedure no drainage is indicated. Re sorption of intrapleural air is so rapid that he has not found it necessary to assurate it.

not found it necessary to aspirate it.

The cases reported by Lenormant comprise 3 intrapulmonary foreign bodies and 2 foreign bodies

Fig. bows quature lin [nning)

of the mediastinum on in front of the posterior part of the sides the other bing situated behind the peri arhum at the depth figures

A sixth case i that of a project landled in the thickness of the diaphragm. In a fatient recently operated upon Lenorman has extra ted by transpleural and transdiaphragmatic lapar otomy a bullet situated in the onvex race of the liver. W. V. BRENAN

The question as to whi h should be prierred the operatory method or the use of the electromagnet for the eventuation of portins of projectiles retained in wounds or in a title does not admit of discuss in. The operatory method is in the majority of cases the most secure the easiest and the least dangerous. In the trachea the cosphagus and intratherance regions howe er in which operation is difficult or impossible extra tion of the foreign body must be made generally by means of the electromagnet.

The case reported by Burk was that of a soldier who in addition to a gunshot wound had two punctured wounds about the level of the tenth right costal. In the right thorax about the livel of the middle of the scapula there was a very pronounced cutaneous emphysema. In the pleural cavity there was evident wheezing which extended to the angle of the scapula. Exploratory puncture was bloody. Resection of the tenth costal released about 500 ccm. of a fortid purulent bloody liquid with little particles of projectile. On recovery from this operation the patient was sent to a base hospital where it was found that the right lung was greatly collapsed and that the pleural wound gave a very foul secretion containing pyocyaneus micrococci. By means of a sound a fragment of projectile could be felt in the pulmonary pleura about 10 cm. from the operatory wound. The rigidity of the thoracic wall did not favor extract on of the

projectile by the ordinary operative method more over the patients a conditi in did not warrant further operatory damage to the lung. The author therefore determined to endenous to withdraw the fragment with the electromagnet. After some fruitless attempts he nucceeded in extracting the fragment which was about 1 5 by cm. In size. A few days after the extraction the suppuration ceased and within a few weeks there was a gradual extensi of the collapsed lung. The patient improved and guised 2 b in weight though there was still some mastills.

W. A Barrouse

TRACHEA AND LUNGS

Green, N. W., and LeWald, L. T. Foreign Bodies in the Raspiratory Tract. 4 Surg. Phila ord, brill, 6ct.

Although Hippocrates inaugurated intubation of the laryan in order to cluver sufficiation, very little of note in the treatment of foreign bodies: the bronchi was brought forward pri 10 to the work Millan in 896. Since that time many laryangologists and surgeous have interested themselves in this pathological entity with the result that remarkable strides have been made both in diagnosis and treatment.

In the laryuged portion of the respiratory tract, the yould construct the lumen. In the ven tricle of the larnyx, objects frequently find fodge ment. The next stopping place is the level of the cricoid. The bifurcation of the traches rurely arreis as beject, as bodies small enough to pass the cords will slip into broachus. The right broachus, from its site and position, is the one most frequently entered. The next point of arrest is in the epitarresial bronchus in the right or the hypar terial broachus on the left or in the trunk broachus on one there side. A small body may penetrate the divisions of the trunk broachus on the notice and the side of the first penetrate the divisions of the trunk broachus must be sought and the residual side.

Foreign bodies may be classified as mineral, metal, or organic. Blost mineral and nextl objects are revealed by the V-ray. Some organic materials, soch as poeces of bone can be detected in the same way. The most dreaded objects, however are the organic substances such as seeds and beans, which cast no sharlow and which well rapidly

According to Bruenings, 60 per cent of foreign bodies occur in children less than twelve years of age. The greatest frequency is at about two years

All recently aprinted foreign bodies abould first be sought by th. Yary and the bronchescope without delay and removed if possible through the month. Should this attempt fail a trachectomy should be done or another effort made by means of the bronchescope. Failing in this also the bronchescope of the properties of the proting of the properties of the properties of the protone in the bone that the foreign body may be coursed out. If all attempts at immediate removal iall, a period anually claspes during which the pantern may develop secondary changes in the pansuch as pneumonal gangence abscess and geneally an overlying empyema. If he recovers for these acute infections he passes into the class of deferred cases, and removal of the foreign body it these deferred cases does not leavy select a cur The lung abscesses must be treated along surplelines, and even then it is not always possible is effect cure but only an amelioration of the affilition.

Canuyt, G. War Injuries of the Larynx an Traches (Les blessures do guerro d. larynx et de l trachée). J. de solt d. Bordesax, g. 6, laxavil, g.

Injuries of the laryout are comparatively rare! war. The startics of millitary surgery of forms war show about 6 laryogeal for 10,000 wounds other organ. In the present war Delormen has state that wounds of the neck comprise about 3 per cent of all ounds and that wounds of the laryor and total are cryptare. Guises found in 100 wounds of the laryor and total are cryptare. Guises found in 100 wounds are cryptared out to the same cryptare of the same cryptare. The laryout on account of this great mobility is able to protect stell from a projectile, but in case it injured the man may die studienly

The most important class of injuries referred t by the autho are penetrating wounds of th laryax, which have for after-effect a traumati stenous either circular or tubular. The treatmen of these laryngostenoses consists either in tracheos tomy laryngostomy tracheolaryngostomy or progressive dilatation. In the latter case after the hir intervention and insertion of the canpula, the cavit is left open. This cavity is packed above th cannul with iodoform gause by means of a dressing The dressing is eplaced at the end I fifteen day or three weeks by a caoatchoor tube the caliber of This is ope which is progressively changed. caoutchouc tube progressive dilatation. When th dilatation is judged to be sufficient, say at the enof five or six months for circular stenoses, twelve to fifteen months f r tubular, the enoutchoue tub is suppressed and a tracheologyngeal plastic opera tion is done which constitutes the last phase of the treatment. W. A. BERTOVAN,

Silvestrini, L. Phrenicotomy in the Treatmen of Som Chroni Diseases of the Lung (L. frenkeotonia nella terapa di akuna malatis croniche del polmone) Riferses med 976 xxxii 190.

In recent years several surgical procedures have been suggested or practiced in chronic lung affections, particularly tuberculosis, such as thorace plasty artificial pneumothoras, and more recent; the phremotomy proposed by Sametruch.

Shventrial has mad experiments on dogs to test the effects of phrenicotomy either unliateral on bilateral, on respiratory dynamics and on the pul monary and disphragmatic tissues. From his experiments he arrived at the following conclusions t Unilateral or bilateral phrenicotomy in dogs is not in itself sufficient to suppress lung movement in a practically useful degree

2 In the early period other respiratory muscle power compensates for the deficiency of diaphragm movement
3. In the later period this deficiency in the motil

movement
3. In the later period this deficiency in the motil
ity of the diaphragm is completely replaced (com
pensation of controlateral and surrogate inner

vations)

4. Neither in the early nor late period is it possible to observe any modifications of structure in the healthy lung.

W. A. REYNNAN

Villeon P de la Operative Extraction of Intra pulmonary Projectiles (Extraction opérati des projectiles intra pulmonaires) J de méd d Bordea x 1916 Extru 7

In a total of 1 100 wounded which have come under the author a observation there were 80 penetrating wounds of the chest. A large proportion of these were carriers of intrapulmonary projectiles. For their extraction the author sometimes employs thoracotomy with costal resection followed by pneumotomy and pleuropulmonary suturing consecutive to restoration of the wall sometimes he extracts under the radioscopic screen following Maudaire's method which he has successfully employed for projectiles having a 10-10-13-m parenchymatous depth.

Companing the procedures he thinks that extraction under the screen is an excellent method truly marvelous in its simplicity its rapidity and in truly marvelous in its simplicity its rapidity and in few minutes sometimes only a few seconds. The patients are up by the fourth or fifth day and pleural and pulmonary reactions are trivial. He reports to successful operations 7 of which were performed under the screen.

e screen. W. A. Brennan

Binet, L.: Indirect Traumatisms of the Lung Due to the Nearby Explosion of Large War Projectiles (Les traumatisms indirects du poumon déter minés par l'éclatement à provimité des gros p. jectiles de guerry. Press méd 1916 p. 3

The author rates some illustrative cases to show that after shell explosions although there is no external injury hemoptivus of more or less gravity may be found in those who happen to be in the vicinity of the explosion. These sometimes may be very grave as in the case of a soldier dying some moments siter a shell burst near him without an external wound and in whom an autops, showed in trapleural hemorrhages with rupture of the lungs and gastice hemorrhage.

Regarding the pathogenesis of such hemoptivisis the author points to two theories (1) the chemical which suggests pulmonary hemorrhage due to intox leation and (2) the mechanical, an alteration in the pulmonary parenchyma b modifications of the atmospheric pressure. Both may occur in association. As regards the latter the hemoptives ob-

served in such cases are due to the presion and are similar to the served in accordants. Butting mention exthe explosion may be duitto impression may be duitto impression are into the lung unit of strong pressure mix cau e a rujeur. The continuous vessel giving mention the hiem publication of the pulmonary vessel giving mention to the management of the pulmonary vessel giving mention.

HEART AND VASCULAR SYSTEM

Silvan C. A Projectile Penetrating into and Lodging in the Heart. D. p. tt. I pet trated arrestat at n. I. R. I.

Silvan reports the a e it a soldier with a gun hor wound in which the prije til reached and remained in the heart. The urpri ing fact was that the functioning of the heart continued to be perfectly normal.

As to the mann r i the provide reading it below that before becoming nx d in the arrha mu le it reached the right ventroular ants where the X-ray examination located it following the liretion of the large read | It is logical to think that it encapsulated and nived it elit in its position with out effect or harm to the involute Y function.

The three interesting cases reported by the author are as follows

The first case was that of a long juxtacardiac projectile resting against the left ventrale and behind it Extraction by the high thora a transpulmonary route was followed by recovery

The second ase was that of a juxtacardiac projetile resting against the left ventrile and below it Extraction by the low abdominal transdiaphragmatic route was followed by recovery

In the third case there was a juxtacardiac projectile resting against the left lobe exterior face Recovery followed extraction under the radioscopic screen.

The three foreign bodies situated in the vicinity of the heart were extracted one across the lung the second by abdominal route across the diaphragm and the third across the intercostal space under radioscopic control.

W. A. BERNAM

Lériche R Ablation of a Foreign Body from the Heart Followed by Recovery (Sur un ca d'ablation de corps étrange du cœur sui ie de guerison)

Re d' ch 916 xxx 4.

Owing to the importance under the present-day conditions of the question of ablation of foreign bodies lodged in the heart, Lénche publishes the

full details of a case operated by him three years ago in which he extracted a needle fixed in the left lobe of the heart of a child of nine years.

This operation shows that the ablation of a fixed foreign body is less difficult than it is thought to be and that no extensive parietal stripping is necessary In the case alluded to he resected a costal cartilage and incised the two subjecent cartilages. The heart being exposed he felt nothing on the ventricles on the other hand above the auriculoventricular all he easily recognized the needle in the lobe. Holding the needle between his fingers he made a small incision, extracted the needle and autured the wound. There was perfect recovery

Lériche thinks that in the case of a bullet a similar procedure could be followed. In the case of a foreign body lodged in a wall, and particularly in a ventricular wall or even a sequestrated foreign body in a corner of the cardiac cavity intervention can and should be attempted. The position can be clarly determined by radioscopy

SURGERY OF THE ABDOVIEN

ABDOMINAL WALL AND PERITONEUM

Outland, I II , and Clendening, L. Phases of the Chronic Abdomen and of the Acut Abdomen.

Interpt. M J g 6 x rall, 337

The authors show a few of the numerous pitfalls that beset the diagnostician in certain phases of the chronic and acute abdomen. Several cases are used as illustrations.

Quoting tables from Cabot's differential diagnosis th conclusion is arrived at that two-thirds of the abdominal tumors large enough to be custly palpated through the abdominal parietes are cither uterin fibroids overien cysts, enlarged gall-bladders. or systric peoplesms, and that one-earth of all such are either tumors of the ovary intestines or liver or tubercular peritonitis, or tumor of the spleen or mallennot oterus.

The authors recommend these tables in the diag nosing of chronic abdominal conditions, ackno ledging, however thei lack of coursey

In old people the flabblness of the bedominal wall must be born in mind as there will be no rigidity in the presence of acute bedominal inflammation.

A ésumé is given of a case diagnosed as tubercu-losis of the liver owing to pulmonary lessons. Operation was performed and sections of the tumor seemed to resemble tubercular processes. Later on in other hands, the case was proved t be syphilitic.

In the acute abdomen there are no t bles of causes and the disgnostician must judge by the

symptoms and his experience.

It must be remembered that lobar pneumonia of the right lower lobe can produce pain rigidity and tenderness in the right sid of the abdomen simulat

ing appendicitis. In ecropic gestation, the symptoms before rupture are always diagnostic and combined with a vaginal examination of sufficient evidence warrant laparot oray

A case is cited of an acute abdomen resulting from perforation of an old ulcer in the transverse colon following fe-cal impaction for eight days.

Another very unusual cause of acute abdomen is perforation of the gall-bladder. However diagnosts of this condition is rarely made before operation.

A case is reported which was diagnosed as acute appendicitu

The rt de closes ith the warning that in acute abdominal conditions a cathatric should never be given and all food by mouth should be withheld. P M. CHARL.

Udaondo C. Serious Œsophagic Sparms in Cancer of the Cardia of the Stormech (Espasmos esolagicos gra es en el cancer del estomago alejado del cardina) Pressa mil Argent 9 6, No. 30

(Exophagi apaims re considered relatively frequent in cream f rms of sensory motor gastric peuroses, as well a in processes a companied by tasue luses.

The anthor had two such cases which developed inside usly and manufested their vistence by the complicit in present a severe spasm of the resophagus simulating in ta evol tion a process of com nlets stenous of the t be. Some of the symptoms wer a progressive dysphagia mucous expectors

tron, profuse sale atton, secondary inanition etc. Cancer of the tom ch, a it yele of evolution, may sie local orsonhame manifestations which may be confused with an organic process in the tube. In the majority of cases on examination with the sound will reveal the purely inactional chatacle which ill be continued by ersophagoscopy

Notwithstanding that all conclusions are only relative the uthor onsiders it important to make a minute physicolunctional analysis of the stomach in individuals of certain age in whom there is found a spastic narrowing of the tube without a determinant cause, rebellions to antispasmodic agents and repeated catheterization at times it is impossible t detect slow processes of gastric degen-RACCL L. Schwartz, A. and Mocquot, P The Treatment of Penetrating Abdominal Wounds in the Ambu lance (Le traitement des plaies pe êtra te 1 labdom n lams les mbulances) Re de h 016 xx\v 46

The authors submit this as a contribution to the question as to the course to be pursued in the treatment of penetrating abdominal wounds of war i.e. whether to operate or to abstain

The arguments advanced against operative treat ment are of two varieties scientific and military The scientific arguments are the tenden of

such wounds to spontaneous recovery the baneful influence of the shock and the bad results given

by operation.

The authors find that spontaneous recovery of abdominal nounds with intestinal perforation is rare and in cases where recovery takes place it is very difficult to say whether or not there was a real intestinal perforation. In the absence of sur gical intervention there is apt to be errors in diag nosing perforating wounds. The fact that certain simple penetrating wounds, or even in rare cases intestinal perforating wounds recover spontaneously is not a sufficient argument against operation if it can be proved that laparotomy can cure wounds which would not have healed spontaneously

As regards shock the authors think that the state of shock in which a wounded patient may be is not an absolute operatory indication because they think that the best means of remedying the grave conditions which the site of shock indicates is to

operate.

Against the third argument the bad results

obtained from operation the author sul mit their own statistics. They have don too lir trotomies for pen trating abdominal you | Of these in are lead and to recovered at hil within three days aft r the operation. In this cases lesions were irremediable. Sever I had fully developed pentonitis they would have hid without pera tion and they died in spite of it

Of the 10 recovered cases o had pen trating in testinal wounds 7 had visceral perforations. Some of these might have reciviled pontineously but the greater part have been cured by the operation an I the auth is think that it require no argument to how that laparotomy is the best treatn at for

ab lominal wounds

The argument of a military nature against oper The I lay 11 arrival of the wounded the hin ulty of in ling asopti conditions the length of the peration and the lift ulty I hand ling hundreds of woun led arm ing imultaneously

The fir t two arguments are cally liposed of The au by good organization and equipm nt thors have not found it is cessary to neglect others in ord r to perf rm lar irot my in an ambulance service. Moreover this procedure require nomine tim than is required in a seriou limb injury

The indications f r operation ar discussed also the hagnostic principles operatory technique and operat ry prognosis. Short details of cach it their to cases are given M. A. BRIK IN

author protests against the st reotyped m thods of treatment of abdominal pain and coli-The great pitfall for the practitioner lies in the fact that many abdominal pains are not due to surgical conditions and secondly in the difficulty of differentiating surgical disorders in their early stages from the lesser maladies. Until a very few years ago the purge was thought to be a very good introduction to the treatment of any disord r abdominal or otherwise

When the practitioner learns to treat all cases of abdominal pain with masterly inactivity during the period of indeterminate diagnosis when he does nothing that runs counter to the principles of treatment set forth when he calls a competent surgeon at the earliest indications for operative treatment, the mortality from the acute belomen will approach the vanishing point

EDWARD L. CORNELL

Quarella, B. An Interesting Cose of Double Retrograde Strangulation (S. di en interessante case di doppie stroummento retrogrado) Gier d Aced di seel d' Terine 0 5, huvui, 38

This very interesting and comparatively rare case occurred in a man who while working was suddenly selred with abdominal palms, names, and persistent wondring. The attending physician diagnosed the existence of strangulated logical-acrotal bernial which he tried valuey to reduce and had the patient sent to the hoordral.

By an location parallel t Poupar's ligament the hernial sace was isolated and found to contain two intestinal loops in good condition of nutrition and only alightly congested. The existence of a hydrocele was discovered in the right testicle from which a citron-colored findle estaged. Of the two loops found in the hernial sac, the right was formed from the contained of the control of the control (about 1 cm) and the terminal tract of the Beum (15 t so cm) the left from a loop of the small intertine about 20 cm. In g.

At operation the abdomen was fou dit contain a quantity of hemorrhegic foul-wellig Haid. By traction of the excum a portion of the ascending colon, normal in aspect and the appendix, which was dark in color evidently by sangularly infarcts, were extracted. The author then proceeded to extract the segment of the intestine intermediat to the two hemiated loops. This for bout one half meter in length was only slightly dilated and blackish blu in color studied with humorrhagic infarcts and was evidently necrosed the mesentery for a distance of 6 to 7 cm. from its untestinal insertion showed identical coloration with profuse thromboals.

The uthor mad a typical psendicetomy followed by resection of the necrotic Internal segment with circular entero-anatomosts. After the reduction of the internal segment in the stadomen the bernfal sac was resected and the peritoceal breach closed by linear satures. The bydroced sac was partly resected. The patient had fully recovered by the seventeenth day after operation.

In discussing this case the auth rat ted that the term retrograde strangulation was introduced by Maydl in 895 to indicate the condition by which part of the strangulated organ is found internally in the abdomen while the remainde is found in the hemilal sac. Maydl reported two such cases and since then several more have been reported and many theories have been suggested to account for the condition. Nevertheless it must be confessed that retrograde strangulation of the intentior remains today e of the most obscure phenomena in the field of survical nathology

The athor thinks that the findings in his own case I we the theories of Lucenstein and Lorens. According to Lucentein the Lucentein and Lorens. According to Lucentein, traction on the two external loops may give origin in the measurery of the interior loop to a springing formation in the form of an are with its concavity toward the ring. Peripherically the measurery would remain free and fluctuant contrally I ward it roof it would find it self exposed to a greater or less tension. A wording and the Lucentein this tension is the impediment to free snapulnary circulation. Lorens thinks that secondary meteorsus of the internal loop makes it rigid so that the peripheric part is constricted and datended causing the production of sharp angle at the level of the areade described by Lucenstein.

Chaput Treatment of Larg Crural Hernias by Padkulated Adiposa Graft (Traitement des groses hernes cru des par la grefi adipeuse pediculies Res d prote 9 6 vols 43

Chaput ands that most methods in use for the treatme t of large crural hernias are inefficient. H n w gets excellent results from the use of fat grafts.

The same incusion is made as for naturnal hernia The perit neum and bernial sac are drawn into the incumed wound supplem ntary thigh incision being in de if required S tures are uncleus f r the obliterat on I the crural ring. He therefore closes it with pediculated strip of fat which is sutured to the edges of the ring. A rectangular strip is cut about two fingers wide and to cm. long the base of which corresponds t the pubes and the inner borde at the media line. The dissection is carried as far as the poneurous. The rectus muscle is increed, the peritoneum tripped from the wall, and the graft introduced. The graft is entured t Gimbernat' and Cooper's ligaments, and to the The summit is divided the posterior crural ring part being fixed t Cooper s ligam at behind the crural vein and the anterior part fixed to the crural ring in front of the vein Chaput has oper ated upon five patients in this v with a cores

Boss Occult Bleeding in Ulcus Ventriculi and Stornach Carcinoma (Bettrag zur Ken inh der okkulten Bittiungen bei aleus ventraculi und Magenkarcisom) Arck f Verd ungstr. 9 6 xvii, Nos. and 3

While there is a very great similarity between ulcus ventriculi and carcinoma of the stomach when viewed essually on closer examination it is seen that th occult bleeding which occurs in both differs not only in the manner of occurrence but also in the form. In the case of carcinoma the bleeding is pensitent while in ulcus there is a relatively quick disappearance of the blood also there is a difference in the intensity of the bleeding in both cases. From a consideration of these two differ entiating characteristics. Boas advances as an essential condition in the diagnosis that examination of the faces alone with regard to the occurrence of occult blood is not sufficient but that the examination of the stomach contents should also receive great consideration. By this procedure it will be possible to reduce the number of unnecessary operations now made in the case of unhealed ulcers which are hot recognized as such, and to have such operation reduced to a reasonable limit to the Big Taylor.

Leonard V. N., and Dayton A. B. Multiple Acute Gastric Ulcers After Using Percya. Cold Iron for Inoperable Carcinoma Preliminary Report of a Fatal Case. J. 4m. M. 4. 1910. N. 1.

In this case rigid application of Percy's cidd main was ineffectual in eradicating the caramona and was followed by death after four days with lesions similar to those of extensive cutaneous burns

The case is as follows. A woman, age 2 (140) children) had had no bleeding since the menopau e at 42 until November 1015. Then she had profuse vagnal bleeding for the days which re-urred once. Further symptoms were loss of weight slight pain, constipation, and painful defectation. Pelvic examination showed the cervix entirely destroyed by a rough firm growth extending far out into each broad ligament hxing the uterus numly in the pelvis.

At operation the technique most recently advocated by Perc was rigidly followed in every detail. On the second third, and fourth days after the operation the was coute gastine dilatation. On the third day there was a unnary fistual and on the fourth day a paralytic leus. During preparation for enterostomy the patient died suddenly.

At autops, the pertioneal cavity contained 100 ccm of serosangulaceous fluid with a little inbrinous exudate at the operative site. The intestines were distered. No obstruction could be demonstrated. The pleural cavities each contained 500 ccm of bloody fluid. There were a few subserous ecchymoses. Extensive pulmonary ordems was present. The stomath was distended with gas. Its mucosa was perforated by about 22 clean round ulders which measured from 1 to mm in diameter. Microscopically the loss of substance extended to the submucosa and was unassociated with am ellular change.

Grossl) and microscopically intact squamous cell cartanoma was found peripheral to large areas of general necrosis. Many mitotic nurses were seen in one area seemingly dead carcinoma was found in the musts of normal looking connective usage. Examination of the regional 1 mph glands re aled no cartinoma.

Ernst N. P. A Case of Congenitul Atresia of the Duodenum Treated Successfully by Operation B. (M. F. J. C., 644)

The bill a by was robut at birth and there was no haston of deformity in hi family. He weighed a soo gram and showed no external sign of any malformation. From the first the hild alway yomited after suckling. On the third day he is k the breast more act; ely than at nr b but two or three hours later he began to yomit with alm it cyplose evidence to the new two passed and the movements ere limited to a small amount of typical meronium without a particle of ingested milk.

At operati n an incision between and 8 cm long was made a little to the left of the mille line After the antenor sheath of the rectus had been laid hare. Mosetig batiste was sewed to the edges of the skin with continu us silk sutur so that the integuments w re completely covered. On opening the perstoneum the dilated stomach protruded into the wound and was triced along the dilated pylorus into the duodenum which was uniformly about two tanger breadths in with as far as it could be traced to the upper side of the tr nsver e mesocolon Below the Am here the intestine reappeared at the flexura duodenojejunalis it was seen to have collapsed to the caliber of an ordinary pencil about 8 millimeters in diameter. The remaining part of the small intestine was examined quickly especially its lower portion but no stenosis was fisco ered.

A duodeno-entero-anterior nastomosis was made A coll of small intestine about four inches below the flexura duodenofelunalis was drawn up in front of the transverse colon and united t the duodenum about the function of the pars superior and pars

descendens

The intestines were held during the operation by Doyen a straight soft intestinal forceps continuous seroserous suture was applied then a continuous suture through all the layers the entire way around and, finally a continuous aeroserous suture was applied on the front. When a stomach-tube was passed through it a good deal of air and greenish fluid was discharged. The intestinal forcers were removed and immediately afterwards the f iu m began to fill. The walls of the abdom: al incesson were united with deep cateut sutures and interrupted salk sutures were applied to the sheath of the rectus and akin.

A few hours after th peration, the infa t was given a weak mixture of milk and water bout 30 ccm. every two hours. H vomited a little several times in the course of the day and t 8 p m more violently, so that the stomach tube was used and a little greenish fluid evacuated. At 7 p.m. an enema was given, but without any result.

The next day he was given one tenspoon! I of castor oil twice and three enemats and had altogether four alvine discharges, which, without any doubt contained digested milk. The child's appearance was good No more violent vomiting occurred but there was slight slokness for some days. The bowels acted daily and the tools soon appeared quit normal. The temperature also fell to normal Five days after the operation th hild was sent home to be nursed by his mother The dressings remained untouched until the fourteenth day when all sutures were removed the wound had healed by first intention

The infant's weight decreased during the first five days oo grams more and was then 3,400 grams or oco grams less than t his birth but afterward it increased considerably more than so grams week continuously for several months. Meals were soon allowed every third hour and when a few weeks had massed, the child could sleep all night without food. He is not remarkably quiet for his age, is vigorous and well developed. His eight one year later Was I soo grams.

This is the second case of its kind in the literature. ED AND L. CORNELL

Carman, R. D. The Roentgenologic Diagnosis of Duodenal Ulcer 4m. J Reestressel 9 6 lil, 5

The author's experience in the last year leads him to believe that deformity of the duodenal shadow is a valuable sign in the diagnosis of duodenal ulcer-However errors may arise from the following conditions () Adhesions or spasm may cause an identical deformity (2) Some ulcers do not produce a deformity (3) It is sometimes difficult or impossible to sufficiently distend the duodenum to d finitely decide whether deformity is or is not

In repard to the first object in the most common cause of deformity is adoubtedly ulcer

To the second objection while some ulcers are so very small that they as hardly be palpated at peration, still there is usually an ecompanying anasm which causes deformity ut of proportion to the lesion and it as be demonstrated by serial adjorranhy T till the can in difficult cases the uthor uses the horizo tal position with the patient prone o n the right sid

Carman has used serial radiography for a year with what he consid to satisfactory results and an

increuse in correct diagnosis

Deformities of the bull come under four beadings () the greetly distert I type resembling a small pine tree () the nuche type where the citual crater of the uk r is 'as bl (1) the incisura type single r bilateral (4) the 'Cry small bulb of smooth conrepresenting in h ontracted duodenum.

In addit n t dued nal deformity the author considers gustri hypertonus hyperpenstalais hyper motil t with a hip residue valuable diagnos tic igns t i oxienal ul er Although none of these ronded as re pathognomo ic of ulcer a proper correl tion of the field go taken in connection with the history go a ling v toward making the 6 ft Gener. diagnosis.

Martini T Chronic Ulcer of the Doodenum and Its Gastric Repercussion (La 1 era cromes del duodeno su repercuados ga tru ! Preus méd Arment 9 6 \ 31 38

The ind ect sympt ms of duodenal picer are those showing a effex alteration in the functions of the

Among the 'linical symptoms that f rm the classical syndrome of duodenal ulcer the most significant are those derived from secretors and motor disturbances of the stomach

Martini employs the analytical method, and studies the gastn secretion both bef r and fter the prestion f th test meal f Ed ald Winther He then tudies the gustric motility by the aid of radioscopy

The exploration of the m thity of the stomach in the uthor cases revealed a marked perataltic insufficiency with a median gustroptoris and an abnormal clongatt n toward the right a hyper functional peristalsis, especially expulsive slow and difficult pytoric evacuation, besmuth being found in the stomach are bours afte ingestion.

The author found it difficult to mak diamous of duodenal ulcer in the presente of the gustrosuc corrhere syndrome of Reschmann which he con siders adaptable to two types of duodenal ulcer-(1) when the ulcer is found attuated toward the pyloric aphincter and (a) when besides its location near the sphincter it is compilested at its lev I by destrictal retraction and consecutive stenosis. A chronic duodenal nicer complicated by stenosis modules entirely the clinical aspect of a simple utler of the same nature. The air ho considers the surmedic or tool as insufficient in 30 pc. con the cases the only satisfactory that multiple can be derived from an action.

The syndrome of castro hypersecret in pronel of the type of Havem is the mile of mainfest at notaclorenal alice. Part LV 2

necrosis, it must be remembered that even a very advanced inflammation of the appendix may be due to an infection of extra-amendicular origin.

due to an inferction of extra-appendicular origin. To make arm that the appendict in the cause of a peritonials the evigantism about the moster and the stomach and doodenum examined. The mere fact that no exudate is noted from this egion, is not sufficient because often an exudate flood itself a pathway by the inclined parts to the left and noth my is found in front or to the right.

W A. Brennan

Guthrie, D. The Prevention of Feecal Platuin in Supportative Appendicitie. A. S. g. Phila v. 6 [kill, 451.

From his experience with \$53 drainage cases in which the uthor has had three facial fistule: Guth ris concludes that the following factors are of primary importance in their prevention.

The muscle-splitting incision should be used except in those cases in which the abscess is well defined near the median line. In these cases the author believes the straight incision should be used

The treatment of the stump. Whenever possible the author has inverted the stump using two rows of catgut and no non-absorbable material. Where this has not been possible he has resorted to the old cull operation, turning down cull of the thickened peritoneal coat, ligating the stump with extent and tying the fold of peritoneum over it.

3 The third factor is drainage. The author uses large soft rubber tubes, which he Jo cas a far away from the head of the excum as possible and aborters them as soon as it is deemed task. Laza tives are never given until all drains are removed. He bell we that gauze does not act as a drain and is conductive to fiscular formation.

Observation

Second E. R., and Conten. L. IL. The Results of a Year' Work in the Treatment of Acute Appendicitis. Cased M 4st J 1916, vi. 4 L.

Ot a cases of acute appendicits operated upon by the subset, one died, one of seren cases with generalized peritonitis. Thus it would seem that the mortality rate from acute appendicits should be very small and it is believed that the important essentials of a n-morrelity treatment consist of early diagnosis and removal at the earliest time possible. The authors with to correct an impression that appendix cases should not be operated upon after the third day unless or sulf. localized abscess has evidently formed. An inflarned appendix should be removed immediately no matter what day of the disease, thus saving a certain large per centage of desperate cases.

A mistaken application of the dictum that the production of a constant symptom of ppendicitis must be avoided. While an elevated temperature is probably always present some time during the course of the attack, it is by no means a constant symptom of a gangrenous or a localized peritonitis. A dead appendix no longer gives the symptoms of appendicitis and the absence of fever has frequently been responsible for delay on the part of the medical attendant.

I versi n of the appendiceal stump is opposed, the stump being potential source of infection and the general pentoneum being better able to deal with it than the tiny sac of peritoneum with which the atump comes in contact after the application of purse strong suture. Inversion of the stump without primary ligation is opposed also, because of the danger of hemorrh ge If the appendix con tains pus but the peritoneum is free a rubber tissue wick is left down (the occum in the presence of a localized abacess t be drain ge is used if generalized pent tis is prese t a drain is always placed to the bottom of the pel rs I all pus cases the immediate use of a stock proparation of mixed infection was cine as urged. I the latter class of cases the Fow ler position and th. Murphy drip are also used and if post-operat ileus is feared, injections of esempe are all ised L. K. ARMSTRONG.

In gen ral Sh w does of agree with the dictum bid dow by Ochmer reparding the time to operate in acut cases not can h ceept Blantie s version— When a case is seen too late for early operation, nd tumor is present and the pulse and general conditi and cat dangerou beospiton, if the tumor is forceasing markedly and there are again of melection spreading, no agreem would besitate as to operation interfere ce is imperative because to operation interfere ce is imperative because general condition are often totally at various with local conditions. (3) the impossibility of outlining the tumor mass with raid beily (4) and, to await the sign finitestion spreading seems to be like locking the tabl feet the bore is stole like

Shaw believes that the time t operate upon scute cases of ppendicutis is mmediately after the diagnosis is mad after the twenty four hour period, opinions and statistics vary which differ ence he thinks, is due to poor operative technique and judgment, poor ante- and post-operative treat ment and deticient comprehension of the underlying pathological conditions. In over 600 cases, so per cent of which were estimated as acute. Shaw has had 6 deaths. He believes that in the surgical treatment of appendicitis there are n hard and fast rules. All preliminary enthansis is contra indicated on ecount of the d neers of sentic dissemination and the increased post-operative tympuny and pain as well as the deferring of the operation for several precious hours awaiting their uncertain action. Where cuthartics have been administered. the muscularis is still active for several hours after the operation terrifically increasing the gas pains and being totally inefficient as a cathartic. He also bolds this true of the so-called high enems."

In the preliminary preparations for the operating

field be believes (1) in a thorough shaving of the whole abdomen (2) a very gentle scrubbing of the abdomen with green soap and a lysol solution making with attrile water (3) application of alcohol packs. The immediate preparation, he believes should be to first mop the umbilical and ingunal regions with benzine sponges followed by fresh benzine sponges followed by fresh benzine sponges followed by fresh benzine sponges for the remainder of the abdomen after drying with a clean sponge a 50 per cent alcohol solution of thacture of fodine is applied followed with a sponge saturated with alcohol to remove the greater part of the foldine (Since submitting this article for publication the author has adopted the use of McDonald's solution)

In the making of lineisions a thorough anatomical knowledge of the part is necessary especially of the innoversation of the abdominal walls since an injury to the nerve supply is far more serious than simple incision of soft parts. In acute case, past the twenty four hour period, the usual incision of choice is the gridition incision modified to meet the individual indication. Where there is a palpable mass, incision is to the center over the mass. It is well to make the incision moderate at first but susceptible to rapid enlargement the author be lieves the low "gridition incision and when necessary the addition of Harrington's extension to be ideal.

He also believes in the center of the gridiron incision being about one inch lower than McBurney gridiron incision for the following reasons (1) the most difficult part of the operation is the delivery of the appendix without rupture (2) the lesser danger to the twelfth thoracic nerve

The external oblique is cut transversely in emer gency this, however being a court of last appeal for it necessitates the severance of the fascia at an angle to the direction of its fiber which, in the presence of infection, means an added danger of post operative herma In chronic cases, and those with in the twenty four hour period and those where the tumor mass is central, or when there is doubt whether the lesion is appendicular or pelvic he makes a mediolateral incision, which he considers the most practical incusion in surgery because its advantages are multiple and its execution so simple He has used this incision in more than 1 000 pelvic and abdominal cases and has never found cause for The following advantages are claimed (1) rapidity and simplicity (2) minimum destruction to nerve supply (3) external strong belly wall left due to muscular interposition and lack of organic injury (4) beautiful exposure and ability to make a general exploration and to perform any ordinary work in the lower abdomen or pelvis (5) absence of

hemorrhage and no tearing of muscles. In cases require demands recourse may be had to one of the three following procedures. (1) through a simple stab wound away from the primary wound make a hole in the muscle for the drain in line with the skin and facial incusion. (2) omit tacking muscle to the median line at the lower end of the wound to the median line at the lower end of the wound

Shaw never drains through a primary wound but always through a stab wound and where the drain is in proximity to the deep epigastric vessel he ligates the same well above and below the drain The d liv ry of a retrocecal appendix he believes can be greatly simplified by mobilizing the lower part of the colon in the conventional manner and tacking it to k immediately after the delivery He does not advise the use of absorbent sutures to bury the tump in the frainage cases but uses in stead tine chromic gut mounted on Dulox needles He believes in removing the appendix whin the same can be done without unlue rik of breaking up ad heatons, and dissemination of infection into the g-n eral cavity is unduly prolonging the operation in the ase of sertic or debilitated patients. The appen heular visceral peritoneum in acute cases should be consider d as septic and handled gently and if possible should be kept wrapped in gauze from the beginning to the end of the operation. Ligation of the meso-appendix is best a complished by either the Watkins stitch or by the author's original titch. Under no circumstances does he irrigat and the use of peroxide of hydrogen he considers little short of criminal He believes in carbolizing the stump but does not follow with alrohol and believes in making the purse string suture ample In cases complicated with dense adhesions, where it appears best to sever the appendix first at the carcal attachment this is done with a knife close against the forcers attached to the distal portion, and the stump is burnel at once. He believes it possible to attach towel clips to the perstoneum and in some ases to attach towel clips to the peritoneum the

skin and gause at the same time
Sugg stions a to the type of drainage follows
(r) In simple cases where there is doubt as to the
necessity a small eigarette drain is inserted (2) In
purulent cases well walled off where the appendix
has been removed a large eigarette drain is employ
(d (3) In purulent cases where it has been im
possible to sever the appendix and there is a well
walled off cavity a good sized tubular drain is
used (4) In cases not walled off a large sized tubular drain with one two or three cigarette drains
at strategic points is used

Drainage tubes should be soft should not im punge with forc on the dobilitated walls of gut and should not come in direct contact with any suture lines involving the gut and should be placed in dependent parts. In cases where the drainage is through a stab wound several strands of silkworm gut are inserted in the lower angle of the original wound where the anesthetic has been unduly prolonged or where the operation has necessarily followed several hours after the ingestion of food castic layage is recommended.

In the after-care of drainage cases Shaw uses the Fowler position and the Murphy drip method using sugar instead of salt solution. In the post-operative care of the wound after four or five days when the discharge us extremely thick and heavy it is sometimes washed out with six or eight ounces of salt solution, to mechanically remove the chief amount of debris. After the first forty-eight bours Shaw invariably washes out and fills all cavities and satu rates all drains with alcohol (U S P) at least once and sometimes twice, daily for the following reasons (1) Alcohol is a harmless antiseptic. (2) It is a mild astringent. (3) By its hygroscopic action it promotes a local outpour of serum with its contained antibodies. (a) Even when diluted with transadates or exudates it makes a poor culture medium. (5) When it first comes in contact with the great mass of superficial débris, it encapsulates large numbers of micro-organisms. (6) It does not render soluble and wash away the primary plastic lymph, either in the healing abdominal wall or the peritoneal Marfaces.

Shaw uses, as a routine, four to eight ounces of saturated solution of magnetium sulphate, at of slowly introduced into the rectum with a No of catheter twenty four bours after the operation, except in cases of extreme debility and saemia.

Perussia, F Partial Hepatoptosis Due to Interposition (La spatoptosi parziale da interposimone) Reference med., o 6, rvnli, 337

Radiologius understand by bepatoptosis the conmonomer of the transformation of intertion of the particle of the transformation of intertion of the particle of the transformation of the particle of the particle of the transformation of the particle o

In his experience and study of this radiologic picture the author has nucleid a certain coincidence of morbid facts which cannot be considered causal and he gives an etiopathogenetic conception of bepatopious which is different from that usually accepted. This coincidence consists of organic alteration of the gastro-intestinal tube. Of a patients studied y aboved a pylone stemous with grave secondary gastrectasis, in the other a three was being project stemosts with how glass stomach due to mediographic stemosts caused by ulceration of the small curvature. In all the 5 cases the interposition of intentinal loops between the fiver and disphragm coincided with a meteroric condition of the colon and the degree of hepatoptosis was proportionate to the intestinal distentil n.

The anthora review the literature of hepatoptods and show that in the greater part of the observations reported in which the condition of the gestrointestinal tract was described the coincidence referred to above was found.

The existence of this coincidence explains the mechanism of the phenomena and leads to a conception of bepartontesis different from the natural accepted one which settlies it to anomalies of the methods of function. The new conception makes the predominant factor of the phenomenon the alters tion of the gaturo-enteric turn.

Partial hepatoptoda by interposition is distinct from the wandering liver of Cantani and from Glenard's hepatoptoda, the first showing a complete fall of the viscers and the second showing a labe ptodis and a deformed unquality mobile liver

Case, J. T. Some Statistics on the Negative and Positive Roentgen Disgnosis of Gall Stones. 4st J. Reculyresi. 910 III, 246

The author statistics may be divided into five groups as follows

r Positive roentgen report of gall-stones with stones found at operation to cases out of a total of 4 making percentage of successful positive diagnosis of 40 per cent.

Positive report and no stones found at operation 4 cases.

Negative report and no atones found at operation 344 cases out of 57 making a percentage of successful negative diagnosis of 95 per cent 4. Negative report and atones found at operation

13 cases, failure to diagnose in 5 per cent.
5 Report of probable gall-stones out of 22 cases 8 were found to have stones, and in 14 no

cases 8 were found to have stones, and in 14 no stones were found, a percentage of correct diagnosis of 36 per cent.

Of the 3 cases in Group 4, 0 had disease of the gall bladder other than stone and of the 4 cases of Group 5 where no stones were found 11 had diseased gall-bladders.

Out of a total of 55 cases with discassed gall-blad der X ray evidence pointed definitely to this condition in 48 cases, or in 88 per cent, while gall-stones were accurately shown in 50 per cent of the cases where they were present.

DaPage, A. Note on Twelve Cases of Splenectomy for Wo. nd. (Not. sur. cas de splenectomis pour blessures de guerre). Bull et mêm. Sec. de chir de Par. q 6 xiii, sq...

The earlier reports from the war zone concerning splenectiony for war injuries showed that the operation was almost invariably fatal. The cause was attributed to perturbation in the economy by suppression of a gland all the functions of which are not yet known.

DePage has up to now practiced is spieneetomics with 8 denths. Of the 1 there were 4 in which the spieno alone was injured and of these there were 3 recoveries. In the other 8 cases the injury to the spieno was accompanied by injuries of other

tures mostly due to shells. The treatment con sists in clearing of the wound dramage use of Daths solution, immobilisation daily dressing Drainage was as from as possible and wheneve there was any increase in temperature or pain, fresh drainage incisions were made.

Of the 4 cases 2 died had amputations in 6 there was complete consolidation recovered with pseudo-arthrosis 2 are in process of recovery. One of the deaths was due t septicemin, and the other to a severe bladder injury the fracture progressing favorably.

No case of ankle injury should be finally diag noted thout this means

Usually more than one line of I actore exists. Most frequently fracture begins in the concave a ticular lacet of the os calcit where it articulates with the wedge like articular facet of the attragatus. The portion of bone posterior to this point is usually driven upward and backward either in a single mass or broken by ne or more lines. Usually there is considerable impaction. This diapterement backward and paved produces flattening of the longitudinal arch of the foot. The fracture may be committed and occasionally may be compound. There may be a tent fracture at the insertion of the Achilles tendon or of the plantar tendon, or on the lattenia spect. It is attachment of the calciance-fibular or lateral teloculcanceal fligament. Them may be a finish like of fracture without displace

The results of treatment of this condition in the past have been poor. The condition is usually an

ment

recognized and neglected. In old cases palliative treatment is adopted such as arch supports for fallen instep pads under the heel for pain in the sole of the foot or operative procedures to remove spicules and projecting callus. In recent cases the normal contour of the bone should be restored For tear fractures the fragments are sutured in position Cases with backward and upward displacement of the posterior fragment (and these form a large majority of fractures of the os calcis) are reduced by passing a urethal sound in front of the Achilles tendon making strong downward traction while counter upward pressure is made on the anterior end of the bone in the sole of the foot The fragments are held in position by severing the Achilles ten don and incasing all in a plaster cast to the knee While the cast is hardening the ball and heel of the foot are pulled toward each other making a high elevation in the arch of the foot. The cast is kept on for four weeks then removed and pa sive motion and massage used daily with hot foot soaks The patient should be kept off his feet for ten weeks then arch supports are fitted in the shoes and he is gradually permitted to put weight in the foot whil walking with crutches

The disability usually lasts six months or more in recent cases properly treated. In unrecognized and neglected cases the disability lasts from six months to two years and may even become permanent.

Groves E. W. H. and Brown T. H. The Treat ment of Gunshot Fractures. La d. Lind 916 cxc, 900

In a typical gunshot fracture the authors call attention to three main characteristics (r) great communition with displacement (2) severe sepsis and (3) pain which becomes intolerable with move ment

The indications are directed to saving life and limb and to restoring function. To accomplish these results four things are necessary (i) immobilization for a long period (2) free drainage and frequent refressings (3) extension in a correct line (4) maintenance of both wound treatment and extension for a period which may be prolonged for several months. In addition the nearby joint should be secretified a so that the limb is in physiological rest and the flectors are relaxed. Mussage and movement of the limb from an early period should be practiced.

Grossly infected wounds are frequent after fracture by bombs and shell fragments also by military ride bullets at proximal ranges. They should be ment should not be delayed for \text{ray evidence if it is not at hand. Missiles and particles of clothing as well as all extraneous matter should be removed. Small punctured and penetrating wounds should be left alone with a simple dressing until further treat ment can be given in a general hospital provided there is no evidence of infection.

In comminuted fractures the authors state with

positivenes that however treely the vendal pened up the hone tragm intended to the mastur. There are only two exceptions to this rule that it moving bone tragm into the whole the artifular only the bone is shattered all looks bone is that treed all looks bone is that treed all looks bone is that the document of the more than the joint and (1) it all the bone is clearly divoid it all a ular nine in and home septiment it hold be taken uit.

Operati chiati n of fragm nt is n trecomment ed. If much minimulti n i pre nt pliting r winng is useles and a mechani l imposibilit and when the fracture i not emminuted it bould be treated by extinsion. B ring h n triplating invarially lads in rist when the unit already into ted.

H W MEYERDIN

Gaille W E Open Operation for Fractures Cd d J M d U S L 9 6 exxix 63

Calle in his article makes a plea for the use of bouled bone for plating fractures. His experiments show conclusively that when any form of transplant is used death of the transplant follows with subsequent replacement of the dead bone by new formed bone which is deposited along the ingrowing capill lairies. Since this is true the author believes that boiled bone plate can be used more successfully than autogenous graffs as they can be prepared beforehand.

Gallie uses a plate made from beef bone curved in transverse section and thicker in the middle than elsewhere. For fastening the plate screws of bone are used these are cut on a lathe. In cutting the hole for the screw is tap similar than the screw is used, into the thread thus cut a polished steel screw is driven this cuts a thread and bardens it by com-

pression so that when the bone screw is put in it does not crumble.

When the bone screw is turned a short stem is left attached to the head, this is tapered and squared to fit into a chuck made like a clock key by which th screw is driven bome. The stem is turned down thin at its function with the head so that it can be broken off after the screw is in place

Gallio also describes a bone holding clamp for retaining the fragments in place this can be better appreciated by reading the original article

FRANC D DESCRIP SURGERY OF THE BONES, JOINTS, ETC.

Walther C. Repetr of a Breach of th Trapestus and Spientus with a Cicatrix Adhering to the Cervical Vertebras (Réparation d'une brèche du trapése et du spienius vec cicatrice schérent à la colonne cervicale). Bull et mêm Sec de chir de Per 9 6 xill, 585

The patient reported by Walther was i jured by a sunsbot and abowed a deep cicatrix about the size of a five fran piece adhering to the cervical vertebre at the crest of the left half I the sixth and seventh cervical vertebra. The trapezius, splenius, and first layers of the thombold had been sectioned by the projectile.

It was impossible to elevate the shoulder and pain radiated along the spine. Walther excised the cleatrix, freshened the muscles and entured them which not only resulted in the correction of the de formity but left a condition which as far as cootracture was concerned, did not differ from the opposite side. W A. BREWMAN

Linberger Hypodermatic Treatment of Joint Injuries (Veber Sta ungsbehanding bei Gelenk verletzungen) Musechen, med Weinsch bill, 33

Linberger reports the details of 8 cases I sovere infuries of the knee-joint treated by Bier's method of continuous hypersonia which was found practicable in field surgery and requires no more time than other procedures for severe wounds. Of the 8 cases y were cured.

This method is particularly useful in knee joint gunshot injuries which are almost always infected wounds. It obvistes and checks the results of infection and thus renders major operations unnecessary Fever abates soon after the beginning of treatment and pain is usually decreased within twenty four to thirty-six hours. The end functional results were good. W A. BRENNAN.

Monchet, A. Treatment of Fistulous Outsitis by th Polyvelent Secum of Lectatoche and Vallée (Le traitement des outlites fatulouses par le strum polyvalent de Lechinche et Vallée). Ball. el unten. Sec de cher de Per 9 6 tri, 898.

The author reports the moderately satisfactory results which he has observed in the treatment of fistulous ostellis by the serum of Lecisinche and Vallée. The use of this method offers doubtful advantages and may occasion great danger

The author believes that the majority of ostelies abould be treated surgically. The mechanical action of the serum which would aid in the climina tron of the sequestre is manifested only when no surgical treatment has been instituted.

The elegatrization obtained after the use of serumized dressings is not always durable. Scrotherapy does not always suffice t bring about recovery and then surgical interference has to be adopted under the least favorable conditions. Moreover the employment of the serum may give rise to accidenta, lymphangitis, erysipelas, and abundant and fortid suppurations from the tract of the osteltis.

serum may be of use in the treatment of the soft parts and in cases of superficial osteitls but it should W A BRENDAN. be used the extrem cartion.

Armitage, H. M. and G. L. Jr. Treatment of Inturies in the Vicinity of the Elbow-Joint. Aus Sury Phila o 6 hml, 506.

The authors review the anatomy of the elbow joint and call attention to the gravity and fre quency of inj ries in this region. They divide elbow joint injuries into

Fract res of the lower end of the humerus (1) supracondyloid fracture (more or less transverse of the shaft above the condyles) (2) T or 1 shaped fractures (3) epiphyseal separation (4) fractures of the external or internal condules and epicondyles

 Lesions of the radius and nine () dislocation backward of the radius and ulus. (2) fracture of the upper third of the ulns, with or without dislocatron forward of the radius (3) dislocation forward of th upper end of the radius (4) fracture of the olecranon process of the nine (5) fracture of the neck or head of the radius (6) sublingation of the head of the radius (7) fracture of the coronold process of the pina.

 Simple sprains of the cibow
 Treatment and surgery of these conditions are discussed. Attention is called to the fact that frequently dressings are responsible for stiffness following joint injuries, and that the best results are obtained by dressings in acute flexion as soon as the acut symptoms have subsided, during which time they are dressed in extension. Passive motion is advised when due to prolonged immobilization. adhesions, etc., though many able authorities ad wise to the contrary

Ankylosis due to excessive calles or displaced fragments demand operation and massage. The use of splints, etc., is advised against

H. W. Mercroson.

Hardouin, P Resections of the Elbow in War Surgery: Functional End Results (Observations de résections d' conde en chirurgle de guerreresultata functionnela éloignés) Bull, et mém. Sec. de chir de Par 19 6 xill, 10s.

The cr elbow resecti as reported by Hardouin are divided into 3 groups () primitive resections (within 24 hours) 19 (2) secondary resections with drainage 25 (3) late secondary orthopedic resections. 7

The first group gave the worst results In 9 cases there was no voluntary improvement 5 are

ankylosed 2 semi-ankylosed 3 with limited flexion. The second group gave 3 good results with extended strong movement 4 with limited flexion 7 ankyloses (5 with half extension or somewhat more, 2 with bad extension) 6 with no spontaneous movement 5 with defective flexion. Of the 25 cases 7 arms are good or fairly good 5 are ankylosed and in 13 the arm can give no real services.

In the third group among the 7 cases 4 showed

good results, 1 moderate, and 2 bad.

Despite the poor functional results the author thinks that resection of the elbow with drainage is an operation of necessity when the life of the patient or the limb is endangered.

W. A. Brennan

Legg, A. T and Ober F R Tendon Transplantation. Interit M J 1016 mill 333

The author's present conclusions are drawn from too cases of tendon transplantation at the Children 8 Hospital, Boston during the five years previous to 1914. Transplantations at the ankle alone were considered.

Under general considerations the authors call attention to the proper muscle balance being sustained following transplantation the inadvasability of waiting too long probably two years after the disease would be best because of the weakness following fixation etc., with braces. Actual paralysis must be determined as muscles may appear to be paralyzed but are only apparently so from over stretching, etc. Leverage and mechanical possibility must be considered.

Operative considerations favor correction of deformity, first, the tendon-transplantation making the wound away from the course of the tendon and inserting it well into the bone after passing under fascia, fat and annular ligaments Insertion with out tension and careful closure of the tissue over lying the tendon are advised to prevent adhesions

Post-operative treatment consists of plaster of Paris in an overcorrected position light massage at the end of three weeks wearing of a plaster cast for three months and a brace two to four months

Causes of failure are faulty technique poor selection of cases, and inefficient after-care. Too long wearing of braces is warned against Six months time is sufficient.

H. W. MIXTERDINO

Jones, R.: Notes on Military Orthopedics Suture of Nerves, and Alternati e Methods of Treat ment by Transplantation of Tendon. Bril II J 19 6 1, 64 670.

The author calls attention to the proper treat ment of nerve injuries causing limb disability. His wide experience before and during the war make his observations most valuable. In his opening para graph he dirells upon the orthopedic features in the treatment of nerve injuries, as nerve injuries rarely occur without damage to the surrounding structures

— bone tendon muscle and skin

In suture of the nerves the following points
should be observed

r The correction of contracture of the skin or muscle and all the anatomical constituents from the skin to the bone on the concave aspect, that is to say on the almormal direction the contracture

2 When possible the freeing of joints from all adhesions and the restoration of the mobility of the joint in all cases where ankylosis of the joint is threatened

3 The maintenance of the paralyzed muscles in a position of relaxation throughout the period of

ecovery

4 The practice of massage during recovery but without once allowing the relaxed muscle to be stretched

He lays especial stress upon the relaxation of the muscle and has found that this elemental principle is often neglected. He says the most skillful operation performed on the most suitable case will prove a fasco unless the affected muscles are kept continuously relaxed until recovery takes place.

He recalls his previous statement that though poliomvelitis may permanently leating the motor cells of the antenor horns of the gray matter and thus forever render the muscless dependent upon them useless this however has seldon been the case and clinical experience has shown complete paralysis with complete recovery and many partial recoveries thus proving that the motor-cells thus concerned suffered only temporary injury

The difference between an overstretched and an paralyzed muscle must be recognized and this can only be done by putting it in a position of relaxation and giving it prologid rest for at least as months. Although many of the principles are applicable to gunshot wounds there is a limit to conservative methods, and in cases presenting a promise of success nerve-auture is advised. The author states that his experience in tendon transplantation in poliomyelitis has been of great value to him in caring for gunshot wounds. H.W. MEYKERDENO

Quént E. Partial Amputations of the Foot for Gunshot Wounds of War (Note sur les amputa tions partielles du pied dans les plaies par p ojec tiles de guerre) Bill et mêm Sec de chir d'Par 9 6 all 538

Injunes to the foot by gunshot wounds are comparatively rare. In the statistics of Nové Josse rand, Gourdon and others in 2516 amputations there were only 110 partial amputations of the foot, and a great many of these were on account of frost bite.

Quenu thinks that in injuries to the foot as in those of the hand, even when the injury is severe there should be no elsate to amputate and when amputation is necessary it should be done in healthy tisme. If there is no appearance of infection, the general rules of surgery should be followed it a removal of the projectile and cleaning the wound if the operation is done early with arrest if the projectile in the tissues, remains by first intention may be obtained even in articular wounds with a rapid citatization and return of the functions of the foot. If there is infection of the joints are supparative the philepmonous foot west be incised and evacuated. If drainings of the strictulation is difficult amput then may have to be done but this articulations are the properties.

The final plantic restoration abould be delayed to several weeks when the field of operation is in a generally healthy condition. This will give opportunity for an economic operation. As much if the calcaneous as possible abould be preserved

Pirogoff operation, either modified or not ppears to be th most desirabl. If A Banara

Pathologically hallux valgus is not an xostosis at all shows no thickening of the metat real

phalanx, but does exhibit an atrophy or erosion of the articulating head of the metatarial

For operative treatment Painter recommends the old flueter operation removing the metatarsal head, and advise the use of a metal splint to prevent riding up of the phalanx on the metatarsal. He condemns the use of training in the burns between the metatarsal and phalanx.

R. G. PARKARD

Cross, C. Golfer Foot. Med P 9 6 lxxxix, 896

Golfe foot is new ame for the old condition of metatarnique and as defined by Cross, is a distortion Journauri of the heads of the second third, and fourth metatarnial or any one of them. In the golfst this condition is due to the first that when making for instance a right handed drue, the player throws most of the body weight over the anterior ports of the left into fo the foot has been elevated at the upsar gr. This weight is distributed mostly to the out half of the arch, including the

mostly to the out half of th arch, including the third, fourth and tith metatarnal heads, and strain m y he produced. This condition of relaxation or rapture of the ligaments of the anterior metatarnal arch, may also occu in any oversued.

The ymptoms actude first shight discomfort to the base of the third or fourth toe slight swelling on the drash surface pain in pressure and a feeling of irritated by 11 tigut. Physical signs are practically epail. Treatment consists in correcting the arch by the application of dry heat holding on the arch by some fierable support exercising the hearth by some fierable support exercising the parch by a confidence of the support of the sup

SURGERY OF THE SPINAL COLUMN AND CORD

Castex, M. R. Vectobral Metastatic Carcinoma Frimary in the Breast (Carcinous ertabral metastatics per primitivo de la mama). Pre se melé Argent g 6 u, 5 pp. 3

The author reports a case in a woman of 4. This toy showed that in October 1915, the left breast had been excited on account of tumo Examination in February 1916, aboved the vert brail column grossly deformed domolumbar kyphosis movements of extension flexion and laterofication, considerably reduced and palnful pressure very painful from the second donsalt the accrum apophysary deviation in all the zone of the kyphosis intense intumescence on both sides of the column in the dorsolumbar zone bland elastic, and very painful.

Three possible genetic causes for the spondylosis, lues, tuberculosis, or neoplasm, are considered. The first two Castex rules out for reasons given and deduced from the symptom tology. It thinks the most of onest the mortisid course, and the actual symptoms fully correspond to a vertebral carrisona process. The f. that the patient had already had neoplasm of the left breast is againforant and although it may be objected that the apondytosis might have existed prior to the neoplasm yet the uthor thinks the fest in this history clearly prove

Vertebral carehoma is never primary it is always accordary measurate. The bervarious on occord of primary carehoma do not stand before anticomognichogos crutichoma do not stand before anticomognichogos crutichoma do post stand before brail metastatic cancer always corresponds to the primary type from the histological dewpoint. It is much more fequent in women than in men, and corresponds with cases of mammary carehoma. The author is away of ordy one case of vertebrail.

that this was of the case

carenoma in which the uterus was the prime focus In similar cases in man the prime focus is in the

prostate or bronchii.

The point of incidence in the vertebral body is usually the spongy tissue and it develops most commonly into osteoclastic carcinoma, but it may take the osteoplastic form. The dorsal and lumhar regions are the most frequently attacked and the process usually extends to many vertebræ

The author points out that a woman operated upon for a mammary cancer may months or year later show nervous phenomena which are a on sequence of the primary neoplasm. He refers to such cases and he thinks that the pathology of vertebral carcinoma can explain all the spondylitt phenomena

The prognosis in this as in other advanced cases is fatal. No reliance can be placed on arseni al radio-activity or colloidal preparations which have always failed in such a condition. W. A. BRE WAY

Schachner A.: Injuries of the Spinal Cord with Report of Gunshot Injury of the Cord at the Fourth Cerrical Vertebra and Successful Remoral of Projectile S & G - Obst o 6 rali mó

The case reported was that of a boy shot with a 2 -calibre long projectile fired from a rule It lodged in the posterior columns of the cord and was successfully removed from the cord at the level of the fourth cervical vertebræ In this paper dealing with injuries of the spinal cord the author emphasizes the following points

While a carefully prepared set of radiographs stereoptically studied will supply valuable data as to the course of the projectile and the probable na ture of the spinal injury from which valuable con

clusions as to the possible existence and probable extent of ford injury can be drawn it is parlonable to emphasiz the warning that the diagnosis however carefull made i treou nily mi misleading

SURGERY OF THE NERVOUS SYSTEM

Sicard J A. and Dambrin, C.: Nerve-Sutures (Sutures perveuses) Bill et mêm Son d k d P 1916 xxil, 96

In reviewing the observed cases of nerve suture for the past 15 months it appears that the classic techniques followed have not fulfilled the expectations held out and that other operatory methods

must be sought to give better results

Experimental operatory interventions made prior to the war - clear sections with a minimum of suppuration - are very different from those met with resulting from projectiles. The lesion is more extended fusion is distant in the nerve trunk the cicatrix is hard and retractable formed at the expense of tissue a long time suppurative and it may even be fibrous or cartilaginous in consistency. The operator may attempt a partial resection and endeavor to make an end to-end suture of such altered tissues which is sure to be a thera

peuti tailure or if a large resection i attempted end to-end suture is not utilizable. In such ase suture par dedoubl ment may be tried but this is doomed to total failure. Unfortunately the cases are rare in which the extent of the nerve injury is so reduced that it is seen within the operatory field and that the ends may be united directly to other nerve fascicules with preservation of the urround ing nourishing tissue. This when it happens is the method of choice and offers the best chances of recovery

Mter having performed a large number of nerve sutures by different classic methods the authors are led to believe that end to-end suture after strict resection of all fibrous parts remains the best method but that whenever such suture is impossible the method of choice is the nerve-graft which may be either by heterograft or autograft

The authors describe their technique of perve

grafting. They have performed 11 such operations since December 1915 but it is too early for an opinion as to the results.

Comet who submitted this report, stated that according to digner published in 15 th Sicard, the actual number of cases in which the authorn had performed never-auture was 3.7 There appears to have been only 1 success in the series so there was nearly 100 per cent of failures. Personally he has made 3.5 interventions for lesions of peripheral nevers during the war 150 nerve-autures, and 2.7

nerve-grafta. Referring only to cases before January 1913, of a cases of complete interruptions, 6 were treated by exection and end-to-end nature. In all there was functional amelioration and in 5 there was a return of mobility Of the other 6 cases a were treated by "Sadewikewerd." In one of these there is partial retoration of motion and semastion. The other a cases were treated by liber ation. In each case the result was all. The endresults of some of his graft cases are encouraging and be will report on them. W.A. BERKELE.

Simmonda Cachexia of Hypophysary Origin (U ber Kachexie hypophysaeren Ursprungs) Historian mei Webssehr a 6 zidi 241

About two years ago Simmonds published the account of a case of puzzling cachesis which terminated in death, and in which the cause was deemed to be an embolic process of the hypophysis.

The case which he now reports he that of a man of \$\$ who for more than a year showed namente and other symptoms. An occult cancer was suspected, Autopay showed that spart from terminal parameter there was a hypophysary temor somewhat larger than a bazelnut which had simost completely destroyed both hypophysary lobes. In the absence of other explanation the cacheria can be explained only by the hypophysary alterations. There was no sign of a romegaly not a ungle caryphile, only the basophile adenoma of the hypophysis polyunia and adjorats were lacking but on the other hand genital strophy and cessation of spermatic secretion and fail of routeful his lat were noted.

Simmonds also refers to a third case of hypophysary cacheria in a girl of 9 with a hasophile adenoma of the hypophysis, a temporary polyuria being the only clinical symptoms. W. A. Brancias.

BLOOD

Beatti, M. Importance of the Lymphocytosis of the Blood (Importance, de la Enfoctoris de la sangue). Rev. Asse. with America and an account of an account of the sangue.

Beatt thinks that lymphocytosis per se does not call for specific treatment. In a symbility patient without symptoms, with the Wassermann and None-Apet resculent negative, but with lymphocytosis in the blood nothing can be deduced from this sign. In the case of a patient without specific symptoms abowing neither globulinuria, not cellular modification in the cephalorachidism fluid, and the two Wassermann rescions negative of with lymphocytosis above in the blood, this picture is not sufficient to effirm syphilis. W. A. Bareras.

Friedmann M: Intravenous Continuous Infu alon at the Front (Ueber intravenouse Dauerin fusion im Felde) Musuchen med Wh schr 1016 lvni 551

Friedmann cites Garré Nowakowski and others whose experience is that subcutaneous infusion of salt solution falls in war surgery at the front His own experience is similar and he has given up that method and used continuous intravenous drip infusion for more than a year and has obtained much better results. The method is illustrated by citing a case of severe gluteal region grenade wound the patient blanched and almost pulseless. The cubital vein is at once opened there being no necessity for ansesthesia. A glass cannula is sutured into the vein and the infusion dripping is regulated by means of a Martin glass ball apparatus When the pulse is felt the drip is regulated to 200 per minute The operation is then proceeded with.

The rate of drip is varied from 10 to 100 per minute after the operation according to the con dition of the pulse and diagalen stropanthin or adrenalin can be added or isotonic sugar solution may be used instead of the saline. Not more than four to five liters of water should be used in from twelve to twenty hours. II. A. BRENMAN

Miller G I: Blood Transfusion Long Island M J 1916 150

In the hope of finding a method of performing blood transfusion which would overcome all object tions to the excellent syringe method of Lindeman the author devised a valve, which consists of a central body a cylinder 15 in. long and 05 in in diameter with two arms extending in opposite directions On the upper surface is a thumbscrew arrangement which slides back and forth on an internal fitting which has two grooves of the same size as the lumen in each arm From the under surface of the central body a cylindrical stem just large enough to receive the tip of a Record syringe projects downward one inch.

The two arms are connected to pieces of 12 F rubber tubing 3 in long. In the distal end of each tube a metal tube is inserted, which fits the cannula and needle used for transfusion. By moving the thumbscrew back and forth the current can

be directed into either arm.

To overcome difficulties encountered in handling and steadying certain cannulæ on the market the author has devised an instrument which is composed of three parts cannuls, hollow needle and obturator The needle and obturator fit snugly and telescope into the cannula. The obturator and cannula are of equal length 25% in. The hollow needle is one half inch longer and is slightly grooved and bevelled to a fine point Three-quarters of an inch from its distal end the cannula is encircled by two rings. The space between is just wide enough to receive a suture which is temporarily placed by being passed through the

skin to hold the cannula in position preventing it from being shoved back and forth during the aspira tion and injection of blood

The cannula, telescoped by the needle bevelled point upward is pushed through the skin and into the lumen of the vein for about a quarter inch and the needle is withdrawn for a short distance to prevent puncturing the vessel wall. The cannula is then driven into the lumen of the vein until the ring on the cannula meets the skin. When blood is observed coming through the needle the needle is withdrawn and if the cannula is not against the wall of the vein the blood will flow freely The obtura tor is then inserted and a suture passed through the skin and tied between the two rings of the cannula If the blood does not to prevent it from slipping flow freely through the cannula it is withdrawn slowly a quarter inch or so

With the donor and recipient cannula in position the operator removes the obturators and adjusts the metal tip of the rubber tubing to the cannulae to A o-ccm. Record syringe is tilled with warm normal saline and air forced from both arms of the valve before adjusting it to the cannulæ The thumbscrew of the valve is then pushed in the direction of the donor's arm the piston is drawn very slowly and the syringe filled with blood thumbscrew is then changed toward the recipient s arm and the syringe emptied rapidly of blood operator continues to alternate the direction of the thumb screw filling and emptying the syringe without disconnecting it from the valve, until the desired amount of blood has been transfused

ALBERT ERRENTRIED

Carter W S An Experimental Study of the Use of Sodium Citrate in the Transfusion of Blood by Direct and Indirect Methods S ik M J 1016 ix, 427

Carter's experiments were upon dogs. His apparatus consisted of an ordinary pharmacists percolator of 300 ccm capacity brated and a perforated rubber stopper was fitted The stopper at the bottom end had into each end a 1-shaped glass tube drawn out to form two can The upper stopper had a nulas inserted into it bent piece of glass tubing inserted into it which served to connect the cylinder with two pressure The pressure bottles were used to control the pressure in the cylinder

At the beginning of each transfusion 50 ccm of a 2 per cent solution of sodium citrate was put into the cylinder and the blood was drawn in by lowering the pressure bottle For the first and second groups a uniform negative pressure was used when filling the container and a uniform positive pressure in emptying t. It became apparent that the most important factor was the length of time the blood was kept out of the body so in the third group the blood was kept in the cylinder a uniform period of time by varying the pressure It was found that the blood should not

be kept out of the body more than on and nehalf minutes at the most

The solution of sodium citrate was compared with physiological salt solution, with Ringer's solution.

and with a solution of hirodin.

In the experiments in which sodium citrat was used in the indirect method the blood was allowed to flow through a paralined cannuls for flash containing s₂ ccm. of 2 per cent sodium citrat

solution until the flask was filled up to the 50 ccm. mark. The citrated blood was filtered through several layers of sterile gauge wet with physiological salt solution before it was introduced into the recipient a velm. Small clots were frequently found on the sauer showing the necessity to this preca-

tion.

It was found to be very important t have can make large en ght give a free flow from the donor, thus avoiding delayed congulation which occurred in the dirated blood after it had been filtered through gause in three cases in which the flow was all w

In Carter's experiments he found

1 That sodium citrate is a satisf ctory anticoagulant when used in the cylinder f direct

transfusion in a a per cent solution

2. That transfusion can be continued from 2.5 to 3 times longer with 2 per cent citrate solution

than with a physiological solution
3 That a solution of sodium citrat is as efficient
as a solution of himdin, as shown by the amount of

blood transfused or by the time of transfusion
4. That sodium citrate does not lessen the coagulability of the blood and is not trice in the

amount used
5 That the congulability of the blood is temporarily increased immediately after transfusion in which andium citrat is used

6. That the lethal dose of sodrum citrate is dogs is about r gram per Lifogram of body weight when dilute solutions are injected and that r concentrated solution the dose is not more than 0.5 gram per

7 That a o. or o 3 per ce 1 solution of sodium citrate is sufficient to prevent coagulation of does not have any toxic effect in the amount used f r indirect transfusion in man. J W Turkus

Begonin, P. and Moulinier R. Arteriorenous Aneurism of the Axillary Artery (Aneurism artero veinc. de la ratire ulbare) J. de med d. Bardi. 9, 6 l. v. 76

The pattent in this case was ounded early in A gust By N vember 2 the dat of the opera tion, the aneurism had the aspect of a justiorm mass occupying the summit of the villa was pul satile and had double bruit which was properated in the pectoral region. The hand was cold, dis colored and slightly ordeniatous. The operation was long and tedrous. The artery and vein were ligated bove and below the aneurism prior to its excision. The compression of the subclavian artery on the first rib did not interrupt the arterial flow After inclaing the pectoralls major and azillary artery were temporarily ligated The ansurism included 3 cm. of artery and 6 cm of vein. After excession the circulation was re-estabtlahed in the limb in better mechanical condition than before the operation.

Attention is called to what the authors term the collateral sign I e. when the circulation has attained a certain value, examination of the collateral vestels will disclose very clear pulsations over ordinarily non pulsatile arteries. In this case the external mammary and the subscapular arteries were distinctly pulsatile. This sign when observed is a valuable indication for intervention and it is a symptom which argues well for a favorable prognosis.

WA BRENTYL

Séjournet Wounds of Veins (Plaies des eines Pesse mid 9 6 p. 151

Séjournet does not favor compression in wounds of vents because it does not assure drainage and favors infection of the wound while allowing the risk of a secondary hamorhage. He thinks ligatur of a large vessel by bringing the return circulation to an abrupt stop in a limb exposed to infection com promises its vitality. Hence his preference is for lateral suture which only narrows the caliber slight by and re-establishes the circulation.

W A. BRENVIN

Graf P: Experience with Vascular Injuries (Erfah rungen bei Gefaess ri tzungen) Be i kl. Chir. 916 xcvill 53

The author gives his experiences derived from 58 vascular wounds observed during the fighting around Warsaw

In these §8 cases, 62 interventions were mude three times arrest of hemorrhage in dying men 43 ligatures 5 amputations of limbs 8 suturings 3 tamponings under narcosis The general mor taility was 25 per cent The carotid externa was ligated six times the carotid interna once and the maxillaris externa twice Tamponide was absolutely necessary in one case There were 15 ligatures and 3 suturings of the subclavian, brachiali and cubitalis for arm wounds

In the leg region 30 interventions were made for 20 injuries 23 ligatures — 5 amputations for infection 5 vessel suturings 2 tamponades under narcoils. Of these interventions 16 were on the femoralis — 11 ligatures 6 suturings. In 4 out of 5 interventions on the populated infection was already manifest and in the fifth case the patient died of secondary hemorrhage after a couple of weeks. In the tibials ligature generally stopped the hemorrhage. In one of these cases amputation are found necessary and the patient died after a few days owing to loss of blood from the stump

Eight arterial suturings were done without any subsequent secondary hemorrhage, infection or death. The author a capterience leads him to think that vacular injuries coming to the field surgeon are under all circumstances to be considered as life endangering. In only the munority can a smooth infection free encapsulation of the blood outlet be obtained and by the development of aneutrans bleeding may continue for weeks. Every econdary hemorrhage even if slight makes an

opening up of the bullet tract imperative. This should be done even if the bleeding ceases. Later hemorrhages may be expected with certainty. Therefore it is always best under narcosis to lay bare the larg r v sack in suspected, and particularly in infect el. cases.

For lean w un is suture of the vessels is the best procedure in leven slightly infected cases may be sutured when the external wound is well trimmed. The vessel must be learly separated away from the avity by muscle uturing.

Figure of the larger we sels must be kept up for two or three weeks especially when the collateral blood flow can be regulated and checked by a proper disposition of the limb

Hyperamia and the procedure of Moszkowicz are adaptable whin there is a question of the development of collateral circulation.

II I BREYLIY

POISONS

Busy Localized Tetanus (D tét localisé)
Bull 1cad d méd d P r 1016 loc 504

When tetanus develops it usually attacks the whole musular v tem. But some cases have been noted in which it has attacked only one part of the body leaving the head free. This type has been designated as localized tetanu.

The author ha found a case which he believes answers this description in a soldier who had the left leg amputated. Antitetaine serum was injected six hours after injur. The wound suppurated and there was some fever. All the usual symptoms of telanus leveloped trismus dysphagia sardonic laughter pain fever and profuse perspiration and antitetain treatment was instituted with an immediate cessation of most of the symptoms. But tend culture showed the piocyaneus only and inoculation proved negative. No tetanus spores were discovered.

The author while admitting the possibility of local tetanus thanks it is difficult to diagnose as tetanus these cases in which more or less extensive contractures are observed with a particularly pain full infected wound WA BEZMAN

Goadby k. The Treatment of Tetanus. Pat

The treatment of tetanus is divisible into two main categories prophylactic treatment and cura tive treatment

The proph lactic treatment aims to accomplish the cardinal points (1) to prevent the growth of the tetanus bacillus in the wound itself (2) to neutralize any poison formed by the organism directly it is formed and before it can attack the nerve tissues (3) to cause as little local disturbance as possible to the parts infected by the tetanus

organism especially nerve trunks

To prevent the growth of the tetanus bacillus
it must be always kept in mind that the organi m

is a strict anaerobe, and therefore free oxygen prevents its development. Wounds contaminated with earth, especially contused punctured, or lacerated wounds, should be freely exposed to the air protected only by very thin coverings. Oxygen in the form of peraxide of hydrogen should be used freely and waste dressings must be burned at

To neutralize any poison formed befor it becomes absorbed by the nerve tissue, a prophylac tic dose of antitetanous serum abould be given as soon as practicable after the injury and before any extensive wound cleaning is performed. It should be administered subcutaneously in a dose of soo U S A units. Since this procedure has been adort ed, very lew cases of terapus have been recorded from the front.

a. Adequate and convincing experiments have proved that the tetanus toxin finds its way along the perineural lymph-channels into the central pervons avetem. As little local disturbance of the wound as possible is therefore indicated if any premonitory symptoms of tetanos have appeared, such as rigidity or local spasm of muscles in the immediate neighborhood of the wound, or an occasional symptom, general rheumatic pains. When definite tetanic symptoms have appeared it is highly dengerous to amputate or perform any operation which opens up the nerve trunks anywhere near the wound.

The chief points in the treatment of established tetangs are

1 The early recognition of the prodromal symptoms. Lockiaw is pearly always a late symptom.

2. To neutralize the poison in the nerves and blood stream, and to extract such as has already become absorbed by the central nervous system.

3 To keep the patient strength up until the neutralization of the poison is effected by the natural defensive powers of the body aided by the adminis-

tration of the appropriate antid tea.

Chief among the early symptoms are local muscular rigidity and fibrillar twitchings sometimes the latter are noticed by the patient himself. In a severe and extensive wound, rigidity due to tetanus soasm may be mistaken for traumatic swelling, but the rigidity in tetanus is usually confined to muscle groups, such, for instance, as the right half of the anterior abdominal wall in a wound of the right groin, the left rectus and the external oblique being fiscoid the deltoid and tricers in a wound of the upper arm.

The most important clinical treatment of tetanus is the administration of the specific antitoxin researches of Park and Biggs have shown the value of the intrathecal route for the administration of

tetanus antiserum.

There is little advantage in administering tetanus antitoxia intravenously as well as intrathecally and from Parks experiments it appears doubtful if tetapos antitorio enters the cerebrospinal fluid from the blood. When tetanic speams are established, intrathecal injection of tetanus antitoxin abould be performed.

Fliteen t twenty com of cerebrospinal fluid are drawn off and the serum, previously warmed to body temperature, is slowly run in by gravity 4,000 to 8,000 U 5 A. units according to the

severity of the case.

The patient must be kept i a darkened room and the utmost gulet maintained. Any shock or noise however slight induces a spasm. Narcotics, in full doses should be freely administered, such as chloral to at Dotassium bromude, 15 atevery four hours, u til the spusms decrease par aldehyde may be giv n in alternation. Morphia may be given addition to the above.

I H. Senas.

Kuemmell Th Res It of Prophylactic Vac cination Against Tetanus (Die Erfolge der Schutmoplang gege Wundstarrkeampi). Berl. W churchy 00 110 44

knemmeli dwels on the conservative course followed by surgeons in the early part of the war and the changes which were instituted owing to the appearance about September 914, I gas phlegmon and tetanus. Very littl success was obtained in the t entment of tetanus and the mortality was very high. Madelung showed 4 de d out of 22 tetanus cases. In different bospitals it ran from 50 to 100 per cent. However, since the wounded have been gi n prophylactic intramuscular injectio of so units of antitoxin tetanus has almost disappeared. I quires show that in one hospital out of 483 prophylactically vaccinated cases there was only one death. one of Kuemmell's field hospitals where there were 372 wounds of a severe nature, du to grenades or shrannel after antitoxin vaccination no case of tetanus developed

Out of 1 555 very severely wounded cases treated prophylactically, there was only o e tetanus case which was fatal. From inquiries among his colleagues Kuemmell finds that only 42 cases of tetamus were known to have developed during the past ten to eleven months although the conditions were the same as before except for the prophylactic treatment. Of these 42 cases o had not received prophylactic vaccine. Among 8 French prisoners whom Kuemmell vaccinated from aix t eight days after they were wounded, there were 4 deaths from

In good many of the cases that hav been report ed where tetanus appeared after the administration of antitoxin, th antitoxin was gi en very late. Protection can only be counted on for fifteen days. and if the infection is severe for nemore than a week. The first protective vaccination must be repeated within seven days if surgical intervention of any kind is made or to be made. If there are further interventions it is well to repeat the precautionary a jection. Knemmell thinks that the relatively small number of fallures after protective inoculation will be reduced with the perfecting of the scrum inoculation technique and avoidance of errors in its administration as well as the early treatment of all suspected cases.

There is only a comparatively small number of individuals who are especially susceptible to the tetanus posson, and for whom prophylactic treat ment is of little avail. For the treatment of tetanus itself no good results follow any known treatment and thus the practice must be to immunize the body against the working of the tetanus poison W. A. REXYMAN.

Robertson H E.: The Present Status of Magnesi um Sulphate in the Treatment of Tetanus Arck. Int. Med 1916 xvii, 677

Robertson gives a comprehensive review of the climical reports of the use of magnesium sulphate in the treatment of tetanus. From a careful study of the Individual reports it is readily apparent that antitetance serum not only holds a valuable place in the treatment of all cases of tetanus but also that the administration of magnesium sulphate by intralumbar injection has brought about a definite decrease in the percentage of deaths from tetanus. The same may be said of the subcutaneous method but the intravenous method has been disappointing.

The deleterious effects of magnesium sulphate is an important factor in its administration. An overdose may result in sudden death from its effect on the heart or its centers in the spinal cord. This accident has not followed the subcutaneous method and as the spinal cord in the spinal cord in the spinal cord in the spinal cord in the most frequent bad effect is from depression of the respiratory center, this can be combated by the administration of calcium chlonde so corn of a 2 per cent solution into the muscles. Physiological salt solution would rapidly give relief or the administration of it mg of physiotigmin or eserin. The good effects of these drugs are not so apparent when the magnesium sulphate has been given by an intrallumbar infection, and it was suggested to wash out the subarachnoid space with normal salt solution.

He quoted Meltzer as suggesting the following dosage Intraspinal, 1 ccm. of a 25 per cent solution for every 22 pounds of body weight. Subcutaneous 1 2 ccm. of 25 per cent solution per kilo As the subcutaneous injection is painful it may be necessity to precede the injection by same local anesthetic as novocaine

DL DEPRAD

Emery W D: Some Factors in the Pathology of Gas Gangrene Laucei Lond 1916 czc, 948.

Gas gangrene is described as the most interesting datases of the present time. It is of equal interest to the surgeon and pathologist. To the latter it is of special interest because it is a disease caused by an organism most virulent under certain conditions and absolutely non pathogenic under others.

The disease may appear in a slight wound and the part may become gangrenous in as short a space of time as two hours when it emits a peculiar disgusting odor. This odor may be thrown out by the
hody of the wounded and the nurses have become
so sensitive to its presence that they recognize it as
the death smell. Death may take place with
profound toximic symptoms in thirty hours. It
is apt to develop much later at the base or after
arrival in the home hospital. The amount of gas
varies. The worst cases show but little or no gas
in the tissues. In others there is much gas under
tension so that the tissues crack lie on palpation.
The lesion may be local with sloughing when there is
no toximia present.

The symptoms of gas gangrene are induced by a hacilius which is almost devoid of pathog nic powers first described by Welch as the bacillu aerogenes capsulatus it is more commonly called in Lingland the bacillus perfringens. Though an ana robe it is not strictly so. It grows in milk the cream at the top acting as a seal to prevent access of oxygen forms spores on media which contain proteids by preference When grown on media containing plucose it forms enormous quantities of gas without depositing spores The bacillus is but shightly pathogenic for rabbits a trifle more so for guinea pigs and is equally non-pathogenic for man in whom it is a normal inhabitant of the alimentary canal causing no harm Furthermore it is present at a certain stage in almost all wounds giving rise to no special pathogenic effects and this is especially true when the organism is present alone and unmixed with streptococcus or staphylococcus infections. Cases of hemothorax and wounds of the knee have been known to recover where the organisms were found in vast numbers and where there was no rise in temperature Such contradictions have caused observers to wonder if the welch bacillus is actually the cause of gas gangrene. All evidence points to the origin of gas gangrene from this bacillus how The bacillus of malignant ordems is at times associated with it but its presence is difficult The mixed infections studied are not to detect specially concerned in the development of gas

Why is it that gas gangrene fails to develop in all the wounds in which its presence has been demon strated? (1) We know that the bacillus is killed by the blood serum and plasma. (2) The toxin of the bacillus will inhibit emigration and kill leucocytes when present in large amount (3) In cases of gangrene millions and millions of bacilli are found but very few leucocytes. (4) Dead and lacerated tissues, thoroughly inoculated with dirt and a large blood-clot are usually found in the worst of the war wounds such as shell wounds wounds bacterial growth will take place unrestrained and if there is no free escape of the toxin it will accumulate to such an extent that when it soaks through into the healthy tissues the leucocytes are killed on the spot growth continues and spreading This condition is facilitated by gangrene is set up interference with the blood supply

explain the reason for the frequent appearance of gas gangeres in the forearm and leg in which the nuncies are enclosed in fibrous aponeurous; I which they are rapidly strangled if swelling takes place therein. (5) Another point to be mentioned as the fact that the totin, when it reaches weln causes thrombous, and the vascular supply is still further interfered with. (6) The mere presone of devitating these is not sufficient to give rise t. the alarming symptoms of gas gangrane but its presence in the absence of drainage offers a had prognodia.

As a treatment early drainage removal of clos and dead tissue encouragement of the circulation re-stablishment of tissue surfaces to health by the use of hypochhorous solution, and promotion of lymph lavage by hypertonic solutions, are the best methods of treating wounds with gas gangene o those that are the extend with this virulent infection.

Ritter Gas Burns (Ueber Gasbrand) Bestr Hi Chir 9 S. cvini, 47

Ritter gives his experiences regarding the frequent wound infections due it be gus bacillus and which be terms gas barrs. The disease is character ized by the formation of gas and by the burning up of the tissues. It should not be termed gas piling mon (councetive-tissue inflammation) inflamma tion and supportation usually accompany the injury but are not a necessary part of the dishest picture. The disease is caused by an anaerobic gas-forming bacillus. Ritter thinks it necessary i emphasize the liability to direct infection from the disintegrated matter of dead bodies vites near the trended.

Gas burns may be noticed very soon after the onest of an injury. The author has found it nelve hours afterward. There are two forms the epi sacial type which develops usually without danger and the subfacial which is always serious. Death may result but this is due not to sepais, but thood infection caused by invasion of the lacillus.

The infection may be strictly local and many of the worst cases are of this type. So h local infections are characterized by an abnormally high umber of thromboes in the beginning of the process. Although such local infections are most frequently situated in the extremilles, Ritter has found them in the brain, lungs, etc.

In 1 soo in juries he observed 4s cases of gas burn 2 were in the lower extremities 6 in the poer 7 in the breast, neck, and abdomen 4 in the brain

4 in the lung

Ritter figures his mortality in these cases as 43 o per cent. According t knemmell about one third of gas burn cases are fail. Ludeck had a mortality of 85 per cent and Frans 534 per cent When death occurs it is usually on the second or third day after the first symptoms are noted.

The treatment varies. In light external cases broad inclains usually give good results. E en in cases of deep-seated injuries repeated incisions with chemical agents will mostly effect a cure, but the incusions, etc. must be thorough, and all pockets necrotic areas, etc. must be thoroughly opened up and excised.

Of 5 cases thus treated by Ritter be lost only

As a prophylactic the utbor recommends Bier a passive treatment

If thinks the best results are obtainable from combining free incisions with the Acts method. His procedure is to widely open p the orifice of the wound and clean we yall debts so that nothing but fresh tissue melet. The trajectory of the bullets, etc. re also opened p as airs as possible. All openings are thoroughly washed with soop and hot water.

The soap is rubbed i to the tisrues and rinsed wy with water. By this treatm in the author had surcess in som, advanced cases which did not present themselves for twenty four to thirty hours after 1 jury. He emphasizes the necessity for rad-cal presents much cases.

W. A. Regunan.

SURGICAL ANATOMY

Roua, P. and Jones, F. S. The Protection of Pathogenic Micro-Organisms by Living Tiesus-Cells, J. Exp. Mod. o 6 xxill, 601

The authors point ut that there are a number of important diseases among them leprosy tubercu losis, gonorrhora, Leishmania, caused by microbic parasites which live more or less habitually within tissue cells. The part played by the bost cells in the life of such micro organisms and also in the distribution within the body of the diseases they induce has obvi us importance They found that it was impossible to make direct a vitr tests with the micro-organisms mentioned and the cells in which they live for the reason that they fail to give rise circulating antibodies active enough to be suft able for the tests. But the problem can be approached, they found, by means of artificial systems, fo example by submitting leucocytes that have ingested bacteria to a bactericidal serum and observ ing its effect on the intracellula organisms.

Their experiments incl ded that of a protection against a foreign antiserum, protection against an inorganic disinfectant and bonologous utierrum and from their work a number of facts seems proven.

Living phagocytes are ble to protect I gested organisms from the action of destructive substances in the surrounding field, and even from trong homologous antiscrum.

2 There is evidence that the protection by phagocytes is largely if not entirely conditioned on their being all ve

 These facts should be taken into consideration in the study of diseases caused by infectious agents capable of living within tissue-cells.

But they finally point out that it remains t be determined how far th protection of micro-organisms by living tissue-cells, especially cells incapable of killing the micro-organisms is important in dis ease processes. The phenomenon may have much to do with the survival in the animal body of organ isms such as the leprosy bacillus which is so often found living within cells of the fixed tissues and it may serve to explain in part the therapeutic difficul tles in such instances. It may throw light further more, on the formation of new disease foci at points of injury in individuals of high general resistance For if an infective agent can be walled off from the action of the body fluids by the protoplasms of a single cell containing it there is no reason why it should not be carned unharmed wherever this cell goes. George E. Bettay

Robertson, T B., and Burnett T C. The Influence of Tethelin and of Other Alcohol Soluble Extractives from the Anterior Lobe of the Pitultary Body upon the Growth of Car cinomata in Rate. J Est Med 1016 xxiii 63

One of the authors recently succeeded in isolating the growth-controlling principle, tethelin, from the anterior lobe of the pituitary body The methods of isolating the substance its chemical properties and physiological actions and the evidences of its identity with the growth-controlling principle have already been published. It has also been already pointed out that the hypodermic administration of emulsified tissue of the anterior lobe of the pituitary body to rate either directly into or in localities remote from the tumors, leads to a re markable acceleration of the growth of the Flexner Jobling carcinoma, especially during the period of growth between the twentieth and thirty seventh days succeeding inoculation. This effect is specific since similar administrations of liver tissue during the same period far from causing any acceleration of the growth of the tumors actually resulted in a slight but definite retardation of their growth.

In view of these results it appeared of importance to ascertain whether tethelin also reproduces the effect of the whole anterior lobe upon the growth of carcinomata, and to that end the investigations which are about to be described were undertaken At the same time it seemed advisable to the authors to ascertain whether any other alcohol-soluble extractive of the anterior lobe of the pituitary body exerts any action upon the growth of carcinomata Three such fractions were prepared and their action upon the growth of carcinomata was investigated, with the following results

I The hypodermic administration of tethelin increases markedly the rate of growth of the pri mary tumor and the tendency to form metastases in rats moculated with carcinoma in this as in other respects, reproducing the action of the whole anterior lobe of the pituitary body

2 Other alcohol-soluble extractives of the an terior lobe of the pituitary body with the exception of the lecithin fraction, exert no appreciable effect upon the growth of carcinomata in rats

3 The lecithin fraction as in previously reported

experiments in which the authors employed legithin obtained from ergs causes evident retardation of the growth of arcinomata in rats

GEOR & E BEILDY

Higgins H L Peabody F W and Fitz. R Study of Acidosis in Three Normal Subjects with Incidental Observations on the Action of Alcohol as an Antiketogeni Agent h) 1.77

The authors all attention to the fact that it has long been kno in this title administration of a car boby frate free diet causes the de elopment of a moderate a idosi in normal per n The expenments in this paper ere de igned to ob ain further data primaril on the production familiosis in lu ed by a carbohy drate free l'et and its effect on the metabolism of normal individuals and incidentally on the action it allohol on uch an acidosis. The subjects made use of were three healthy men between the ages of 3 and 33 years The diet whi h consisted chiefly of engs butter meat ush and sugar tree cream was practically carbohydrate free. It was prepared with great care in the liet Litchen of the Peter Bent Brigham Hospital, under care ul supervision, and was served in an appetizing manner. The subjects endeavored to eat about 3 500 calones per day largely of fats vith the idea of getting a high degree of acidosis but they did not relish so much food and on some days could not take it all. The general plan was to make observations on the gaseous metabolism and urine on one day when the men took an ordinary mixed diet then on three days with arbohydrate tree diet, then on one day with carbohydrate free diet plus whiskey and mally on a sixth day a diet with the same protein and caloric content but with much of the fat replaced by carbohydrate

Total nitrogen in the unine was determined by the Kieldahl method. Urinary acidity and ammonia were tested by Folin's methods. The hydrogen ion concentration of the unne was determined by the method of Henderson and Palmer Acetone was distilled by a method suggested by Scott Wilson and utrated by the Messinger method. β -oxybuty ric acid was estimated by the Shaffer and Marriott method. Bang a micromethod for blood sugar was used and Marshall's urease method for blood urea. The alveolar air was taken by the method of Haldane and Priestley with a Siebeck valve samples two at the end of expiration, and two at the end of inspiration were taken before and after the morning and afternoon metabolism experiments and just before the subjects went to bed at night The gaseous metabolism was determined by means of the Tissot spirometer and the Haldane gas analysis apparatus.

In three healthy subjects a carbohydrate free diet caused the development of varying degrees of The acidosis was shown by a lowered acidosis CO2 tension of the alveolar air by an increased urinary excretion of ammonia nitrogen and of actions bodies, and by the increased titrab! achility of the urine. The achiesis was accompanied by sub-jective accessions of malaise, an increased oxygen consumption a negative introven balance increased pulse-rate and increased ventiliation. Alcohol given to the subjects on this diet in desage comparable it that used for clinical purposes did not stop the progress of the achiesis on how any antitation there was not accessed to the progress of the achiesis or how any antitation there was further increase in the oxygen cost imption and in the disagreeable subjective symptoms.

Pellegrini E. Intestinal Function in Pancreopathic Conditions (Funcionalita testinale pancreopatici) Cirs. seel siel Milano, 9 5, li 6 5

The pancreatic function must be studied in two ways according to the fluks which pass from the gland into the intestine and coording to the wider and more general action which the products of internal secretion services on the organism.

The author states that a thorough investigation of pancreas functioning has been carried out in Hangiliano a clinic in the University of Geroot. The results of our various standpoints will be published from time to time. The methods of research are described in great detail as well as the clinical histories of ten pathents and some controls, the results being elaborately tabulated.

From the results the author draws these concin-

sions

In determinate panetratic lessons the copening is tableau is constituted as follows: (a) stock in the last with abundant follows: (a) stock the last with abundant allocatury residue excessively steator-thoric with desquanatory ments: (b) stock inch in numedized salmost wholly of ster coldin with a reaction principally sthaline: (c) those inch in numedized in of undigented carbon-thoric control of the last control of the control of

3 The coprologic picture above that in parameter disease climination of water is profoundly modified poteolytic, surplylytic, and especially steatorrhesic powers are greatly diminished the muckedytic power is lowered the external functions of the parameter are totally compromised.

of the paracres are locally components.

3. Rechrocally it is certain that the index of the lesions or the insufficiency of the peaceres must be sought in the diminution of the digestive power especially for fets, and in the diminution of the nucleolysis of ingested mests.

W A. BRIDDAY

Auer J., and Meltzer S. J. The Intravenous Injection of Magnesium Sulphat for Ansesthesis in Animais. J Ery Mol. 19 6 xxill, 64

The effect on animals of intravenous injections of magnesium sulphate was investigated by the au thorn about ten years ago and its use in this way in general was discouraged. However a series of experiments made by the authors with intravenous injection of magnesium sulphate in cases of experi mental tetanus, and the meager but satisfactory experience which Kohn and Straub had with the empl vment of this method in cases of tetanns in human beings, induced the anthors to take up the experimental study in animals of the employment of magnesium suinhate by intravenous injection for the purpose of producing anesthesia. This was done as preliminary test for the dmissibility of studying the exclusive use of intravenous injections of magnesium sulphate as a means of produc ing or at least inducing anesthesia in human beings. Their experiments seem to justify the following general conclusions

1 By the intravenous injection of 41,000 magnessum sulphat into dogs at a certain rate a stage can be reached where the abdominal walk are completely relaxed and when section of the hdomen and stimulation of sensitive parts of the parietal perit neum do not produce pai or electi any rea tron of the snims). At the same time pont neous respiration may still be maintained within normal limits and the lid reflex be fair or even normal. In this state intratracheal intubation for art titlal respirat on can be easily accounplished. This stage may be attained in twelve t fourtee manutes when the rate of injection is about s com per min to. When this stage is attained the rat of njection should gradually be reduced otherwise acone or later spontaneous respiration will be bolished and by a furthe maintenance of the rate of injection all the skeletal muscles may become paralyzed

3 When the injection of magnesium is continued for a longer period, the paralytic effects of the magnesium injection will set in even when administered at a slow rate.

3 The paralysis of the capirat ty fu ction is readily met by intrapharyaged insuffation which is easily executed even without training in this procedure r by the method of intratracheal in suffation, if executed by one trained in its manage-

4. When the respection of the animal is accomplished by soundistion, the paralytic effect of the magnetium may be sholished fairly rapidly by an intravenous injection of about o come on a 1,000 calcium chlorode solution or it may disappear slowly after the infeation of the magnetium solution is discontinued for some time. The latter mod of disappearance may be favorably ancelerated by an intravenous indusion of 60 t oo com, of a 1,000 colorable participation of additional subplate.

5 The production of auxiliaria by intravenous injection of magnetium sulphar about not be undertaken unless an appearates for intrapharyngoal insuffiction is at hand because in exceptional cases the datappearance of spontaneous reprintion may be one of the earliest consequences of the magnesium infection. 6 The injection of calcium chloride should not be employed in cases in which the subject shows cardiac imagificiency. In such instances moreover injections of magnesium should not be used for the purpose of anzistens at least not until greater experience has been acquired in the employment of this method.

Pellegrini E. Stercobilin (Sulla stercobilina) Cl u med ual Milano 916 liv 791

Pellegrini presents some of the results obtained in experimental researches on intestinal function carried out at Maraghano's clinic in the University of Genoa.

The results were obtained from observation of patients in whom there were more or less notable gastro-enteric disturbances. The methods followed for the estimation of urobilin in the urine were those of Mareschal Huppert and Hammarien and for bilary pigments those of Gmelin and Nencki Gmelia s method of blood examination was followed

The results show that there is an agreement in the conditions of elimination between atercobilin and uroblin in conditions in which these pigments are eliminated normally. This normal urofoccal elimination entits in spite of disturbances of the diges tive apparatus caused by gastric enteric cardiac and other lesions. In hepatic lesions stercobilin diminishes rapidly until only minute traces are left and icterus may or may not be present. In such patients the elimination of urobilin takes the form of pathologic arobilinaria and this is particularly noted in the case of pancreatic subjects.

The facts appear to show that hepatic conditions notably influence the elimination of uroblin and that in cases where sterobilin is absent the elimination of uroblin is pathologic WABRINNAM

Gates, F. L. and Meltzer S. J.: An Experimental Study of the Additive and Antagonistic Actions of Sodium Oralate and Salts of Magnesium and Calcium in the Rabbit J. Exp. M. d. 1910 xxiii 053

On the basis of the hypothesis that magnesium favors unhibition of the various functions of the nervous system, Melizer and Auer studied extensively the action of magnesium salts upon various animals. In injecting magnesium sulphate subcutaneously they found that a certain dose which varies with the species of animals is capable of producing profound anzithema and paralysis from which the animal recovers. For rabbits this dose amounts to about 1.5 gm of magnesium sulphate (NgSO and 7 H₂O) administered in a molecular solution. Larger doses cause the death of the animal as a rule by respiratory paralysis. With an effective but non-fatal dose in subcutaneous injections the development of the depressing in hibitory effect as gradual and facility.

hibitory effect is gradual and fairly slow

In the course of their studies Meltzer and Auer
found that calcium which is chemically closely

related to magnesium is biologically apparently the antagonist of the latter. When calcium is injected intravenously shortly before or immediate by after the respiration stops into an animal which has recaved a fittal dose of magnesium the animal will recover in less than a minute provided of course that the circulation is still effective during the calcium injection.

The problem which the authors have endeavored to solve experimentally in this study is. Can the depressing component of the calcium precipitating oxilate be brought out by a simultaneous administration of a subminimal does of a magnesium salt? Their perimental study seems to have firmly established the following facts.

I Subcutaneous or intramuscular injections of sodium oxalate in subtoric does when administered to an animal which has r-cived a subminimal dose of magnesium sulphate produce profound anisation and paralysis of long duration although the usual effects of sodium oxalate alone are of a stimulating character. This fact is in general in harmony with the results reported by Starkenstein who however seems to have used the combination of the two salts in one solution namely that of magnesium oxalate.

The combined injections of subminimal doses of sodium oralized and magnesium sulphase produce a strong reduction or even at times a complete abolition of the conductivity of the motor nerve endings

3 An intravenous injection of calcium salts brings on a recovery from the profound and prolonged effects of the combined action of sodium oxilate and magnesium sulphate which is as prompt action as is observed in experiments in which effective doses of magnesium alone are given This fact is the more noteworthy since depressions of long duration produced by prolonged continuous injections of magnesium solutions alone do not respond very promptly and effectively to calcium injections.

As will be recalled the starting point for this investigation was the hypothesis that substances which are capable of precipitating calcium—a biological antagonist of magnesium—ought to be capable of increasing the depressive effect of mag nesium The authors experiments proved that this This would seem there assumption was correct fore to justify the interpretation that the augment ing action of sodium oxalate has its cause in the ability of the latter to precipitate calcium and thus increase within the body the amount of unantagon ized magnesium. However they state expressly that this view is for the present still no more than a hypothesis and does not exclude other possible interpretations of the facts As they pointed out it speaks against this hypothesis that oxalates do not produce phenomena of depression the toxic symptoms produced by oxalates exhibit distinct signs of increased and not of decreased irritability

GEORGE E BEILDY

Lawie, D. The Appearance of the Pressor Substance in the Fostal Hypophysis. J Esp. Mol., 10 6. xxiil. 677

It has been demonstrated that the pressor substance of the posterior lobe of the hypophysis is secreted by the pars intermedia, a derivative of the pharyngeal pouch. The present study was under taken by Lewis with the bope of determining at what period in fortal life the pressor substance appears and of correlating the cytological changes in the para intermedia with the establishment of secretory function using the appearance of the remor substance as an index. H found that the hypophyses of pigs just before birth were large enough to permit of separation of the two lobes, but in the earlier states this was impossible. order to secure uniform material for injection the extracts were made from the entire gland in all instances. The glands were obtained fresh and extracted in absolute alcohol to remove the depressor ambstances. After extraction was completed the alcohol was filtered off and the residue dried in a The dried residue was kept in small desicentor

bottles until desired for use when a solt solution extract was made for intravenous injection. As a result of his experiments Lewis concludes that the pressor substance of the hypophysis is so marked in the pix fortus measuring 175 mm, that it seems probable that a feetus of this length is independent of the secretion of the mother a hypophy da. Gross E. Berray

Afberti, O. Tubercular Boefflornia —a Clinico-Experimental Study (5ulla bacillenia tuberculare). Clin. med. tiel Milhano, 9 6 H 73

A question which has occasioned a great deal of discussion in recent years is that which refers to the presence of the Koch bacillus in the direulating blood of individuals attacked by tuberculosis. The auther reviews the voluminous literature commencing with Willemin a animal experiments in 1868 down to the present time. In his opinion the discord which exists in the findings of the different authors is to be explained by faulty methods in the technique

employed. He therefore undertook to carry out a series of experiments following a rigorous technique de signed to exclude possible sources of error He examined the blood of 50 individuals, of which 10 were unquestionably tuberculous, to were suspected and to were clinically healthy. In 35 cases the complete research was made double microscopic examination by the methods of Staubii-Schnitter and Rosenberger and parallel with this a biologic test comprising inoculation of the blood in the peritoneum of guines pigs.

In the other 5 cases the research was limited to the biologic test alone. Bacterioscopic examination in the 35 cases gave 5 positive results with the Staubil-Schnitter method and 3 with the Rosenberger

method.

Biologic tests in the 50 cases and with 78 guines pigs have given a manifestly positive results. Commenting on these results the author thinks that tuberculous bacillamia is met with very infrequently and is only manifested in tuberculous individuals it is an inconstant and transitory phenomenon which ought not be considered - at least as far as chronic tuberculouls is concerned as a true septicamin, but sumply as bacteramia of little clinical importance. Toberculous bacillamia has no relation t the degree of gravity of tuberculous lesions and has n practical value from either the point of view of diagnosis or prognosis. W A. Barringan

Descomps, P Epipioon and Pericolitis (Epipioon et pericolite) Res d chir., 10 6, xxxv 100.

For some years past many articles have been written on the role of pericolitis in the pathogenesis I chronic colitis and tasis. Inflammations and stasis in the colon usually localize in certain go es which I vor them, the terminal ileum and initial segment of colon, the transverse colon, and colonic angles.

In this large te citory there is special segment in which inflammation and tests occur in the majority of cases. The is the right colonic segment. anatomo-physiological condit one found there are of capital import nce and show the part played by the epiploon and therefore by epiploitis in the production of pericolitis and consequently of colitis and stasis in this segment.

The author therefore devotes the greater part of his articl to a study of the anatomy of the epiploon including the arteries, veins, and lymphatics.

Walther and his pupils have at various times from 1898 to the present shown the connection of epi ploitis and chronic colitis, and Descomps himself basing his remarks on 36 observations of Walther has shown the preponderant part played by the emiploon in the pathogenesis of pericolitic phenomene and the favorable effects produced by epiploic resection and liberation of pericolonic adhesions as a complement to appendectomy

There are two ways in which the couploon may be involved. First, by the formation of adhesions with the neighboring organs and especially with the right colon. Such addesions may be primitive, i.e. anatomic in type, or they may be pathologic, inflammatory adhesions. Of this latter type are the restricting bands, derived from the epiploon, which give rise to the so-called membranous pericolitis. The second way in which the epiploon may be involved is less known but not less important. It may become inflamed and scierotic without forming pericologic adherences. The loss of supplement and mobility of the epiploon gives rise t pericolitis and stasis. This type is frequent and in the most recent statistics of Walther this non-adherent type was found to times as against 8 of the adherent W A. BRENBAR. type.

RADIOLOGY

Bogos, R. H : The Treatment of Epithelioma of the Lower Lip Interest M J 1016 xxm, 114.

Epithelioma of the lower lip however innocent in appearance is nevertheless cancer and often shows a degree of malignancy that is not usual in epitheli oma in other situations. It seems to be rather a regional than a local lesion. The lymphatics which drain it should in every case receive the same atten tion as the visible lesion. Until recently the best routine treatment has been early surrical removal of the ulcer and lymphatics Today the general practitioners commonly refer lower lip epitheliomata for radium therapy because they can be successully treated by this method.

At first pioneer work had to be done and the disappointments were many. Radium was scarce the apparatus elementary and the limitations many and serious. Only cases of which surgery despaired built their last hope on radiotherapy The results were necessarily uncertain and a severe test of the new medical faith and hope were excellent results that justified the hope of the physician and the confidence of the patients consequence with our present supply of radium the powerful transformer and the Coolidge tube we now stand on firm scientific ground and radiotherapy has a definite place in the treatment of malignancy To-day the radiotherapeutist has a broad and on vincing clinical knowledge of his subject author is convinced that at present radiotherapy is the best routine treatment for epithelioma at any stage and he also believes that this will be the ulti mate decision of every modern physician. wishes however to caution against haggling radiotherapy of lip cancers as much as against hagging surgery of them Radiotherapy to be reasonably successful, demands competent application. Radiotherapeutic treatment of lower lip epithelioma was discussed at a recent meeting of the American Dermatological Society and it was agreed that it is a legitimate and successful treat ment in properly qualined hands. That epithelioma can be eradicated by radiotherapy has been dennite ly proved and in advanced cases it offers more hope than any other method. Cures have been effected in far ad ranced cases but the sooner a precancerous change is treated the better prophylads always being the safest and the surest. It is only fair and just however that at present no one should attempt this treatment without adequate previous training and experience under proper direction.

The technique must in every case be adapted to the individual patient and his needs. Scientific dosage is a matter of physics and of therapeutics. Physical dosage can be measured exactly but therapeutic dosage depends on the technical and practical judgment of the physician. As an instance in point the author prefers radium used locally for epithelioma of the lower lip and for the adjacent glands radiation with the Coolidge tube. One

capsule is placed inside another or | | and another on the outside of the up to seture conflete irradia tion Usually the first rea tion uff es for healing a moderate lesion but the s ar must be healthy phyble without retraction and without before a case can be in idered limitally cured. The treatment of the adja ent glands must never be Any partial neglected even for the small | t le ion removal of an epithelioma must b ndemned

The author's conclusion are as I llows t kvery cancerous ell mu t be er dicated it the tre tment of epithelioms of the lo er lip i to be successful because expen n e ha hown that this epithelioma is a regional rather than a lik I lesion. All precancerous lesions shoul! be tr ated by

a method that lea es no scar whate r

3 Many hold the result of ral otherapy to be as good and even better than tho obtained by surgery and that urgery hould be resert i to only in selected cases

There are a number of radioth rapeutists who have had suffin at expen a e with epithelioma of the lower lip and who have obtained results that justif them in considering radiotherapy a perfectly I gitimate method of treatment

5 Inethetent work as it is being lone by those who have simply bought the usual apparatus and received some instructions in its use from the manufa-turers cannot be too emphat all denined nor too strongly deprecated

Boggs R H: The Treatment of Tuberculous Adenitis by Roentgen Rays. \ 1 If J 19 6 UN. 10 6

As the end results in cases of tuberculous adenitis treated by the roentgen rays are generally satisfactory Boggs believes many cases that are subje ted to surgical procedure could be better treated by radiation thus sparing the unsightly scarring with the not infrequent sinuses which when long delayed in healing are often finally referred to the radiologist As is well known operation is often followed by local recurrence and at times ri es rise to a general tuber ulosis the diseased glands often being of wider distribution than the clinical signs indicate making it difficult and at times impossible to remove them. The contrast is marked and it as is alleged oo per cent of these cases are permanently cured by radiation, it would seem that this method should be adopted as a rou Radiation in these cases should not be confused with that employed in the treatment of malig nancy, and while hard rays are to be used they should not be given in massive doses as the general system must dispose of the products of degeneration and it is better not to overload it, especially when as a rule it is greatly impaired.

Since the rays are not bactericidal, the beneficial effect must be produced by destroying tissue of low resistance thus rendering the soil barren but attention is called to the fact that Crane has ad vanced the theory that by this proces an autogenous vaccin is set free and this is given in explanation of those instances where a tuberculous process at some distant point from that treated will likewise disappear. The observation has also been made in cases where subercle bacilli have been found in the sputum, subsequent examinations falled to show their presence. While treating these cases. especially those about the neck, careful inspection must be made for local sources of infection in the month and throat had teeth, and swollen totalls but it is by no means necessary to remove every swollen tonail for many will improve after the glands subside When a chain of lymphatic glands has been properly rayed the glands and vessels undergo a fibrous degeneration with almost entire oblit ration, with no marked influence upon the surrounding tissues. Attention is called t a series of 344 cases collected by you Mutschenvack er where operation was found necessary in only o per cent. Mathews is also quoted and his nive rea sone against operation re given. Bogge has also considered the nosalbility of mistake is discrease but calls attention to the fact that such conditions as Hodekins disease and sarcoma also call for radiatio II S NEWCONDE

Gerber I Th Use of the Polygram in Gastroduodenal Diagnosis. Ass J Reculeval 9 6

Gerber for the past several months, has been using the polygram method of Levy Dorn modified somewhat by the use of modern instrum maris and technique and has found it almost indispensable in gastrod odenal examinations. He makes only two exposures on a single plate, with an interval between exposures of about eight seconds. This may be lengthened somewhat in cases with very alongship persuasists or hortened but when the persistable is extremely lively. The polygrams are made in both the errett and the proto positions.

In the normal at much, the passage of the peristaltic waves can be seen in a most graphic manner The two outlines cross and recross each other in such a way as to show clearly that every portion of the muscular wall is taking part in the peristaltic conduction. Thus it can be seen whether or not there is any Bewege galef ht or regional lack of motility In chronic gastri ulcer the area induration will show definitely as portion of the gastric wall that does not tak part in the peristaltic cond ctivity Craters or niches stand out prom inentity Incisure will show as a permanent in cutting easily distinguished from the criss-crossing peristaltic waves. In duodenal picer the character istle delormity is sharply shown. In east the curemoma, both filling defects and defects of mortlity can be observed by this method. In noting pressure from extragastri tumors, distended gall-bladder etc. the polygram may be of considerable assurt

It might be objected that all the above information can be noted on the fluorescent acreen. This is certainly true in some cases, but in many others and some types of duodenal ulcers, the information is either very difficult or about byl impossible to obtain from a fluorescopic study only. Beaties the polygram affords a permanent record. In other words, it offers the advantage of serial plates with out the great inconvenience and expense of obtaining a large and complet serial.

The uther does not by any means offer the polygram as a substitute I rathorough serial study but he does believe that it will in many cases asreconsiderable time trouble and expense for those who coafine themselves chiefly to the roentgengraphic method in the study of gastrod of nal disease.

Newcomet W 8 Th Comparative Valu of Roentgen and Radium Radiation in Thera peutics. in J Rectional q 6 th, rol

Adde from the fact that rocatgentherapy has been brought to high degree of refinement in comparison with radumtherapy there are cases with a space to fall within the distinct province of each in superficial epitheliona, the method which gives the best results in merchy a matter of technique but in cases of carefroma in the cavities of the body radium is without a peer

Upon purely clinical grounds, all things being equal, the t entment of all cases may be divided into two classes

Those n which a localized radiati n is desired and in which these radio-active elements are t be

preferred.

Those calling for diffused radiation over a mo c o less stended area in which roentgen radia.

tion a t be preferred.

Modification must be made in both depending upo the depth of radiation desired.

It has been previously stated that the difficulty of comparing these two forms of radiation is due to the wate variation. It etchnique but generally speaking, the results are obtained from radium with less damage? I surround g tissues than similar conditions treated with rooming radiation.

The idea seems prevalent that enormous quantities of radio-active element are necessary to produ e-results. While large quantities re-destrable the fact remains that a mall quantity judiciously applied will often prove of greater benefit

In coaclusion if might be fairly stated that an exact comparison of the two forms of radiation is entermely difficult due to the wide difference in exchangue and the wide variation of results reported by statous writers in both fields this is further confused by the fc it that many findividuals employing these radio-active element have had very little experience; general radiology. From the author's personal experience and observation, however its still appear in that there is and will be a field for both forms of radiation as well as a very broad common ground where both will yight results equally de

Stewart W H: Roentgen Dingnosis of Obscure Lesions of the Gastro-Intestinal Tract 1 m J Roents not 1016 iii 202

The tendency of roentgenologists of today to ignore the clinical picture and depend almost entirely on the fluoroscopic and runtigenographic had ings in arriving at a diagnosis has prompted the author to make a plea for the more general use of every means available in every case combining the runtigen interpretations with the symptoms and laboratory reports before an attempt at diagnosis in made. Too often what apparently was a clear case roentgenologically has been proved to botherwise when compared with surgical or post mortem findings.

In order that it may be possible to render valuable ald in the diagnoss of gustro-integrand lesions especially the large number of borderline cases in which the patients suffer from pain and distress in the right upper quadrant and which may be caused by laid any gall bladder diodenal or appendicular disease it is necessary that every effort should be made to educate the medical profession to refer their cases to the reentgenologist for diagnosis and not to testinct his investigations to any one part of the gastro-intestinal tract. Just as a stone in the left kidder may give rise to symptoms on the right side so may the cause of symptoms in the stomach be found in the appendix or in the lower colon the refore a negative diagnosis cannot be accepted as final until the entire gastro-intestinal tract ha been examined

Stewart presents a series of cases illustrating the cardinal points which he has attempted to I ring out namely that a thorough physical examination and complete history together with a record of the laboratory reports be combined with the recording at final conclusions. This series consists of several interesting reports of cases accompanied by illustrative roentgenograms which show conclusively how the roentgenograms which show conclusively how the roentgenograms which show findings in the case would have gravely erred in his diagnosis.

Holding A. F : Roentgen Deep Therapy in Mulig nant Tumors. 1m J Roentgenol 9 6 iil, 9

The author's report covers cases which have been observed duning a period of three years including not only malignant tumors but also non malignant diseases sinch as lupus vulgaris keloid acne vul garis evophthalmic gotter myoma etc. In all cases of non malignant disease, with the exception of myoma couphthalmic gotter and tuberculous dantitus and in cases of superficial malignancy the author urges the use of physical methods rather than surgical for the reason that with physical methods which include reentgemetherapy coagula methods which include reentgemetherapy coagula methods which include reentgemetherapy coagula

tion and the ultraviolet light a cure is obtained with the best cosmetic result with ut harmorrhage or opening up the lymphati vessels without pain or the need of an anaesthetic and without loss of time from employm in or happital c nin ment. The result as h wn in the tabulations are very convincing.

The author claim priority in the treatment with the rountgen ray of ar in ma testi of t ratoid origin in 1 arotif gland tumor—ith v ry pronoun ed meli rating effect.

Another group of cases in which improvements his e be nish with a eith se of intrithoracie saresmata and ar momata. If thing urgs the employment froming interprinal of these cases even the misthopeles frinalla ertain digree of relief and be oftained and some may be even symptomatically urs!

In summing up the series of case, the following conclusion, are reached

- The most important point in connection with the use fight, all methods for therapeutic purposes it that they aid nature to cure superficial malignant turn is much better than surgical methods.
- 2 Under roentgen deep therapy it is a ommon occurrent e to have tumors undergo retrograde meta morphosis or e en to disappear
- 3 In hopeless cases these physical methods enable nature to effect marked amelioration of the symptom
- 4 Occusionally this amchoration of symptoms
- 5 The amelioration of symptoms is distinctly worth while
- 6 If these physical methods ameliorate the symptom in hopel as ases patients having operable lesions should not be denied the benefits of these physical methods after operation.
- 7 Two forms of tumor not previously reported in medical literature are markedly ameliorated by roentgen deep therapy namely carcinoma testis of teratoil orimn and carotid gland tumor
- 8 Every effort should be mad to perfect the technique and the use of a flux ants to increase the number of symptomatic cures and make permanent the ameliorations WA EVIS

MILITARY SURGERY

Hagedorn O Finding of Position of Retained Bullets (Steckschuesse und ihre Lagebestimm g) B i ki Cki o 6 v. u. 546

Retained bullets are most frequently found to be shrapnel and they are almost always found to be encysted probably owng to the inflammation caused by the foreign body aided by the blood accumulated round it giving rise to the formation of a cost

The first question arising is whether or not the bullet should be remo ed. The most important objective disturbances indicative of removal are disturbance of motor function and the signs of

vascular or nerve pressure. In the presence of such denegrous symptoms and serious functional disturbances and when the built can be reached without further severe destruction of tissue it

should be removed.

For localizing the position of the foreign body two roentgen pictures in different projections are usually sufficient, the intersection of such projections giving the line in which the body lies, but when the bullet lies in the frontal part of the head, in the shoulder or other positions of very irregular contour this method is unsatisfactory and the apparatus devised by Weise has in such cases given good results in the author's practice. The method is male and satisfactory in its results. W A RECEIVANT

Holl A. J., Keogh, A. H., Pilcher, E. M. Surgery In War Reyel A my Medical Corp Blakista Son & Co Philadelphia, 10 6

This small octavo volume of \$83 pages is a summany of the surgical experiences and conclusions of the present European War by Major Hull and a number of other well-known contributors

The author states that on the bacteriological side Sir A. E. Wright a work as shown by recent our sical developments has revolutionized the method great developments has revolutionized the method of treating sepsia. The object of the wo k is to give members of the profession unacquainted with war surgery an insight into what is being done in

military bospitals.

Col. E. M. Pilcher points to the definition f military surgery which is after all but the surgery of gunshot wounds, with the broad interpretation understood in military parlance viz. inj ries from bombs, hand grenades, and everything set in motion by an explosive compound, as well as wounds from projectiles emanating from rifled arms, both great and small. The vast difference between civil and military surgery is due to the immense difference in the conditions under which the work is done the one hand there are conditions in which the environments dominat the surgeon, and on the other conditions in which the surgeon dominates his surroundings. The civil surgeon operates under conditions approaching an aseptic ideal whereas, the military surgeon a field is seldom suspire but almost always precarious. The wounded man, tho gh he may be fit physically is often exhausted by the fatigue and privations of campaigning when h is stricken on an injected soil on which he is ant to be for days before surgical aid can reach him next subjected to the trying influences of long and often improvised transport, during which proper food, good nursing, and (avorable climatic con ditions are frequently absent. The surgeons dif ficulties are most trying. Hospitals have to be improvised in the beginning of the campaign. These are often overcrowded from the sudden accession of wounded, which arrive when least expected. The overcrowding often brings scarcity of load and sur gical supplies. To add to the difficulties at hand, the wounds, which are all infected and in a class to themselves, are of manifold varieties, occurring in all parts of the body and involving every tissue.

The foregoing facts justify the claim that military surgery is a special branch of surgery Moreover every campaign has conditions reculiar t itself These are distinguished by the moral psychology of the combatants as related to the intensity of the fighting the numbers engaged climatic conditions the character of the con try whether hilly or flat and above all the character of the implements employed in inflicting wounds.

In the present conflict the magnitude of the campairn has brought the virile manhood of all the countries involved to the front and with them the most capable surreons in the world. In this little volume we find how valuable has been the assistance of the civilian members of the profession to the Di rector of the Medical Services of the British Army and incidentally to the medical world.

A notable point in the present war is the way in which the bacteriologist has developed his indispensabl services t the military surgeon. His value the physician and the sanitarian in campaigns had been well established but never before has the bond between the bacteriologist and military sur econ been observed. Infertion and the wound have linked the two together and to achieve success they most work hand in hand. It was through the rational and indispensable work of Sir Almroth Wright and his collaborators that an effective treatment of gunshot wounds has been worked out. Failure to properly arrest infection in war wounds at the beginning of the campaign demonstrated that our antiseptic methods were at fault, and it required the steadying influence of the bacteriologists to direct

surgical endeavor along proper lines. Military surreons in the United States who treated gunshot wounds in the region of the great plains. under cloudless skies, in pure at on soil that had never seen a plow were seldom troubled by the complications of varied infections. Likewise the Brit ish surgeons who followed the armies in the Boer Rar gained experience in infection that served no purpose when compared with that obtained in a campaign fought with a great preponderance of wet days, upon a soil artificially sown with bacteria. largely of the facal kind. This condition has made the labors of the bacteriologist indispensable to

those of the surgeon.

The nature of the weapons has played a very interesting rôle also. To future generations the present conflict will be referred to as the Great War but to the surgeon it will be known as the l'ointed Bullet War Although pointed bullets were used in the Turko-Balkan War and other minor conflicts. the present war is the first in which it has been unfversally and exclusively used in both machine-guns and the military rifle. There has been seen all the ugly wounding effects which were foretold as the result of experimental work. Compared t effects of the ogival jacketed bullet of the Krag Ierpensen type its shattering effects on bone is

better marked its tendency to turn an impact makes it more destructive to soft parts in the chest and abdomen its high velocity and flat trajectory cause explosive effects at longer ranges and it is more apt to break up. When it disintegrates after striking side on it causes wounds not unlike those cause I by dumdum bullets a fact which has brought about charges of inhumanity on all sides such as those which have been heard at the beginning of all var ever since the advent of the high-power military rifle. Accusations of inhumanity have been made more especially against the pointed bullet used by the British army because disintegration of this projectile shows fragments from two separate nu leione of lead in the body of the envelope and the other composed of aluminum occupying the point of the envelope. The British Government ad pted this bullet some time ago for the reason that being a trifle longer than the other pointed bullets it offers more bearing surface against the rifle barrel and thereby is steaded in flight. It is doubtful if the mere fact of a double nucleus adds to the tendency to disintegrate. Those who have experimented with all types of pointed bullets are vell aware or the highly destructive effects which have been brought about by the so-called spit e bullet nr t adopted by the Germans It is doubtful it the pointed bullet of one army is more destructive than that of another

Another remarkable feature of gunshot wounds in the present war is the large percentage of artillery wounds from shrapnel and high explosive shells and to these might be added the wounds caused by bombs and hand grenades. Wounds from these projectiles are attended with a great deal of con tusion hæmatoma, lacerated and devitehzed tissue. They are prone to extensive suppuration, which in turn makes their treatment difficult and laborious in active campaigm.

The statistics of war wounds have been withheld by the cennor so that nothing is given with which companson can be made but assurance is given that results are satisfactory and that improvements in wound treatment are being made very rapidly

The bacteriology of all wounds may be said to be one of environment and for that reason the bacter iology of war wounds is similar to the bacteriology of the terrain on which the battle is fought amount of the infecting dose will depend upon the alze and character of the wound and the degree of contamination of the skin and clothing ations on the vestern front are being conducted in farming districts in which the soil is richly manured with the facul matter of animals and man consequence is that the virulent types of nucrobes which find their habitat in such refuse are very prev alent Broadly speaking the organisms found in the clothing skin and vounds of men are of the aerobic or facultative anaerobic kind and also the strict anzerobes. The first include staphylococci streptococci bacillus pyocyaneus and the members of the colon group and to the second belong tetanus bacillus bacillus of malignant adema the bacillus aerogenes capsulatus of Wel h and the inferter minate series to hich gas gangrene is attributed

The exact robe placed by the clingroup has not been determined. The act not clapby lococy trep! I and other propens organisms is well known in their range in the tissue they outried use in in circumanate be to hear no certain anater be to hear he concerned in the production not grapmen. The brught about 17 per on on one in the present war and the eight of the right of the clinic transfer in the present published in the meritage of the proper his present published in merch his reparation the clinic levidences it tetanum mahigrant dema organg nargene.

The pref rma ion the cress antorgan may it is the merett thourgeon their to to the territization to the turner and all meteral used in the treatment of the void proper. The spors of malignant oddmates that be persured to occord a half hour. These of bailed perfringers require in emitties being. The prefeteations in dry void inscharge remain indicated from months and in the confitt in the beome relation so that autoclaving a really the new energy of killing them. In addition to their resistance it steril instance the anaerobes elaborate forms locally had do in tenter the flood stream until late. The fact is of alue to the surgeon and the radical methods of vound treatment employed in all infected wounds at prefern far yielding explent results.

Tetanus bacilius is the nost important of the malignant anaeroles. The t vin is produced locally in the vound and is carned all not be perpheral nerves to the entral not us not time septically to the cells of the medulla and ponsitationing itself instito the anterior comula cells connected with the motor nerve supplied the wound area so that the first 5 imptom of tetanus is a cramp in the injured limb

The antitoxin is deni ed from the serum of horses that have been immunized against the toxinneutralizing effects of antitoxin vith toxin is a mathe matical process the strength of a given antitoxin being estimated by the amount of it which is required to protect a gi en weight of animal amainst a simultaneous injection of a lethal do e of toxin for instance i cm of the Pasteur Institute antitovin vill protect 1 000 000 000 grams of mouse against a lethal dose of tetanus town and the therapeutic dose of this preparation is to to 100 ccm. The presence of tetanus is first heralded by the character istic symptoms when it is too late to be effected much with antitoxin It is much earier to prevent the union of tetanus toxin with nerve-cells than to unlock the combination after it has been made hence the value of a prophylactic dose. One can not go wrong by administering antitoxin at once when the nature of the soil where the ound as in curred is known or the presence of bacteria such as bacillus aerogenes capsulatus or other spore-bearing bacilli are found in the discharges. These are nearly always in association with bacillus tetanus the latter is difficult to find in a wound.

If teams has developed, the dose may not be fatal, or there may yet be free toxin in the central nervous system which should be countersacted by aptitudin jalgered in the lumber sac. A good plan is to give an injection of o to 15 ccm. of antitioxin in its lumber as and too com. Intravenously in one or two injections as rapidly as possible after the omet of the symptoms. The additional intravenous dose insures a high concentration of antitoxin it the body fluids and a rapid and more intense citon on the toxin. The administration of antitoxin must be supplemented by thorough englication of the infected focus, since it is uncleas a administer antitoxin probability of the probability of the control of the infected focus, since it is uncleas a administer antitoxin it etams bacilli are left in the woods.

The bacillitus of malignant ordems is at times found in wounds, under entiable conditions. There is intense serious evudation in the muscles and sub-custacous tissues the mechanical pressure of which, with the rapid development of the bacilli, cause obstruction of the vessels and republing gengere. It is possible to prepare an antitoria against malignant ordems, but if has never been used therapeut cally

Bacilim erogene capsulatus (Welch) or as it is sometimes called, bacilim speririogens is frequently found in the wounds of this war in association with the bacilius tetanus. It causes free evadation is serum with abundant gas production. The estit ing emphysema spreads rapidly simppling up the cellular tissue and permeating muscle. The me chanical pressure. I the finsion and gas obstruct the circulatum, with resulting gaugene.

While bacilius crogenes capsulates is the chief agent in the custom of gas gangeree examination of wounds will at times reveal other gas-producing microbes. The latter are prone to appear in a counds where death has resulted from profound t vernice of the country of the count

The shattering effects of a shell-wound or the explosive effects. I a wound from the military rifle at close range in the thigh for instance, is a good ex ample of the ideal conditions for anacrobic infection. The projectile carries soil contamination covering skin or clothes deeply into the tissues, shattering the bone, the fragments of which acti g as secondary projectiles, carry infection into pockets in different directions. The harmatoma, contusion laceration, and devitalized tissues provid for the growth of bacteria ideal conditions in a number of foci which are closed by prolansed muscle and other tissues. and thereby rendered inaccessible to the sirdifficulty of removing the bacteria from such a wound and of preventing them from obtaining a footbold and elaborating thei toxins must be obvious.

The bacteria can be removed from such a wound only by free drainage with frequent washing with antiseptics. The advantage of the flow of lymph promoted by such gents as hypertonic asilines and custof (hypochlorous add) has been well demontrated in this wa. The use of ensoil is particularly I wored since it adds it is lymph lavage properties, that I being and which is in itself inimidat to the production of todien. It also opposes the absorption of it kind by the flow of tymph which it induces and by relieving the local tissues of suddate it prevents the mechanical presure on the vascular supply which is a contributing factor in preventing geogram.

The use of vaccines against anaerobic infection is not attended with success. The patient is quickly overwhelmed by the toxins, long before the vaccines as have any effect. The rôle of vaccines use more in built ining up resistance against pyogenic organisms, such as at phylococci and streptococci, in cases of

long continued suppurat on and fever

The general condition of the wounded as dealt with largely from the standpolar of shock and in this expectally it author is partial to the teachings of Crile who be were that shock is a condition of ex haust a and for blood pressure which may be caused by poun harmorrhage sepans, worry and fear if has shown that pounds atmust can reach the that the control of the brun-realt in consequence of brain-cell shaustion, there is derangement of rancor metal manufactured in the standard of the brun-realt in consequence of brain-cell shaustion, there is derangement of rancor metal manufactured blood pressure.

T prev at hock he prevents painful atimuli from rea hing the brain-cells. Painful atimuli may rea h bra n-cells during general anastitesia but they may be blocked by means. I focal anesthesia. Crite has cluborated many m thoch of anoch-succlation, as it is called all being ttempas to guard the brain cell from exhauston by blocken the arrices eather than the contract of the contra

dum to lutalize it

Ande from local amenthesis the administration of morphine befor operation is employed. This lowers the receptivity of the nerve-cell. Morphine is a sheet ancho in preventing shock given in k-gr doses with 1, 50 gr of scopolamine which may be repeated if the patient shows by training or rapid breathing that patient it mill are skill reaching his tree.

The ext measure employed t prevent shock is t maintain the blood-pressure. This may be accomplished by pneumatic contra ances not suitable in war. Bankinging of the extremities is beneficial in failing circulation in the presence of shock.

The pressure may be maintained by transfusing blood (Crile) which is better than saline solution, which exudes from the vessels and may occumulate in loose tessues bout the abdomen in sufficient

quantities to embarrass respiration.

Adrenalin may be added to the solution to be transfused and pituitary extract in appropriat doses has been used. Crile says that strychnine stimulates the brain-cells and acts harmfully alcohol is not much better Camphor and caffeine are u ed

by some.

At the first aid station the hamorrhage should first be arrested the gross soiling of the wound re moved first aid dressing applied morphine given to relieve pain and fixation applied wherever possible the use of alcohol and strychnia should be avoided but the patient should be given h t tea or caffeine Fluids should be given to ustain blood pressure

At the clearing hospital all serious vour is are re-dressed under an anxisthetic Patient with in pound fractures are in used to favor free drainage and care should be taken to appl a well fitting splint that will not cause pain. When deemed nec essars or advisable it is well to use some form. I regional anaisthesia. This may be pra-ti- I upon those who have been operated on or in evere fractures to avoid shock. The addition of potassium sulphate to the local anasthesia solution will I noth en its effect. Morphia in transport is empl. ed to ward off pain and shock. Its use protects the brain cells from continued painful stimulation salin infusion with the addition of adrenalin is useful in shock after hæmorrhage otherwise pituitars ex tract should be used

At the base hospitals patients are examined a to their general condition, the temperature, and the pulse rate. If they are comfortable, they hould be allowed a period of rest unless there is eviden e of gas-gangrene. Compound fractures are \ raved and when necessary to remove the dressing and splints these should be reapplied under anisth his

Extensive lacerated wounds without tra ture should be put at once into a saline bath vith the addi tion of eusol when the discharges are ery offend e This is good for sepsis and it avoids pain hi h f l lows frequent redressing

Shock is prevented by warding off the on litions

that cause it pain sepsis and hæmorrhage Pain is relieved by proper dresting proper fixa

tion, and the use of morhpine Sepsi is a oided by

ample drainage

When shock is caused by loss of blood saline solution should be administered at a temperature of 112 F with 10 to o drops of adrenalin to the pint into the rectum, cellular tissues or a vein it the symp-

toms are urgent

Before operation morphine gr with atropine should be administered hypodermatically. If the patient is to undergo any severe operation, local and regional anaesthesia should be employed. For this purpose one may use infiltration with novocaine per cent with adrenalin chloride added. If to this is added potassium sulphate gr to to each ounce the anzesthetic effect is prolonged and pain after operation is lessened. The use of urea and quinine is sometimes employed by Crile for the same pur pose in lieu of potass um sulphate. Instead of in altration around the main nerve supply implication in the cauda equina may be employed for the benefit of cases of operation on the lower extremities In

filtrati n of the ti ues hould be done ith a large vringe o that force may be exerted to distend all the lay T t tis ue and this ma be facilitated by making un erpre ure with the hand

Cutting with a hirp knite auses less shock than tearing to u and all manipulation should be gentle One en ma be u ed in lap e and the patient s

aseptic in from 3 t 5 days and the edges can be brought together with strips of plaster e compound fractures treated by this method

become clean and can be made to heal like aseptic fractures. The principle element of treatment of large scotic

wounds is the establishment of adequate drainage and the removal of foreign bothes and dead tissue. The latter may be removed by cutting away with scissors or by curetting. The whole wound may be be excised with advantage in some cases.

Wound drainage an important factor in the treat ment of wounds is practiced more satisfactorily at the base hospitals. The drainage should be provided with all necessary counteropenings. ber dramage tubes are preferable to gause drains, which are and t clost. Loose woven cott it bandage is better than gause. One end of the bandage is placed in the wound and the other is carried in a bowl containing a little saline sol tion. The wound is kept wet either by an irrigation drip or by fre quently pouring saline int the wound, and when dependent counteropens g has been made rubber drainage t be is passed through the wound and the bandage is mad to slip along side of this tube Impation of wounds naures a more steady meth

od of f eeing the wound of toxic matter and to this end the osmotic action of hypertonic solutions is taken advantage of The flow f saline in and out of the wound continuously removes the film of torde and the eby limits t me beorption. The wounds found most suitable f r treatment by con the our irrigation are impound fractures and deep septic wounds, especially of the ppe arm and thigh Fomentati as of bot born acid may be alternated at times with the oth methods of treatment especially when the w n do become at gwish in healing The bath treatm at of wou de induces healing

by increasing the blood supply to the part Regions like the face rich in blood supply heal faster than other part lik the feet for instance. Hypertonic sol tion has t great extent replaced the antiseptic bath and it is deal fo wounds if the limbs below the elbow and knee Continued too lo g t renders the tussues sodden and is thring to the nations, and it is ot pacticed with patient in serious condition The bath may be alternated with fomentations at

night or it may be enlaced by irrigations in the day The open treatment of wounds consists i placing a laye of wet gauge over the wound in lieu of the old gause wool ind bandage which acts as a septic poult ce

T almost f pl wounds by existen. treatment of compound fractures cranial and joint ounds has been very much modified by the employ ment of excision. The sooper the excision is made the better because later a large bank of inflamed infected tissue surrounds the wound. In such cases hypertonic solution will render the wound ready for operation in 4 t 48 hours. Co tra-indications to excusion are marked pocketing in the wound and the exposure of vascular or nerve-trunks or of bone hich it is inadvisable t remove. In any case excision f the oiled edges I the kin superiscial turns and

Hospital at Constantinople during which time

they made as a surgical interventions. Among the 222 operations were o amputa-tions 4 of the upper arm, of the thigh 4 of the lower leg: 10 resections, 5 of the knee-joint 6 of th ankle joint 3 of the shoulder joint 1 of the elbow r of the wrist 3 exarticulations, of the phalanges of the thumb a of the shoulder joint rr cranial trepanations 4 vascular operations (ligature of the brachial) for peripheric septic

hemorrhages a previous to exerticular operations s resections of ribs, 5 laparotomies (3 of these enucleations of the eye cystotomies)

The other cases included invisions, currettings, sequestrotomies, luxation, reductions etc were also some epididymectomies, and testicle resections for infections. The operative mortal ty was 11 25 per cent 5 deaths. In the 9 amputations 8 died, 4 s per cent - s upper arms, 3 thigh 3 lower leg. Of the 15 resections, s died, 11 75 per cent - of the knee-joint shoulder Of the laparotomes, dree of th dred, to per cent. Of the trepanations, 3 died, 7 per cent The other 11 deaths were in typical operations and are not specially enumerated

There were 6 cases of gaseous gangrene, 4 of cerebral abscess 6 suppurating fractures CREC of projectile extracted from the bladder As general rule all these wounded arrive in the hospital in a more or less infected condition. Of the cases of gaseous gangrens 3 occurred in amoutations 1 with amyloid degeneration for empyems. In one ense it was necessary to amputat 2 days after a resection. The uthors think that in cases of doubt between resection and amputation, as the organic renstance is very low it is better t resort to ammotation at first because it is better to lose a limb than a man. II A BRIDGAN

Lériche, R. Integral Operative Statistics of Sur-ginal Service at the Rear (Statistiques opéra-toires intégrales d'un service de chirurgle de l'arrière) Lyen chur o 6, mit, 103

In the two rear hospitals of which Leriche had charge oo wounded were received between Septem ber 16th, and October 15th, 915 All those received and operated upon within twenty four bours of injury recovered. The others were mostly received from two to five days from the tim of intury and of these 7 died.

All the wounded had received antiteranic scrum at the front. All later received a second injection and even third where there was a late intervention.

No case of tetants developed.

There was only one case of gaseons gangrene This was in a man who had lain five days on the field. He was cured.

Of \$8 cases which the author considers definitely cured 133 have recovered their physical strength almost completely 55 have a physical value more or less diminished - loss of a limb, eye, etc. W A. BREKKAY

Cutler F J The Surgical Disabilities of Troops in Training Precilieser Lond o 6 xevi sea.

A large number of mutilating gunshot wounds of the face have occurred during the present war. Many of these have been complicated by fracture of the mendible. The usual method of treatment is by wite splints fastening the teeth in positron. So many of these cases however result in loss of bone either from immediat description r from subsendent in fection, that it is often necessary to fill in a consider able can in the mandible. This is best accomplished by transplantation of hone. The wounds must have soundly healed and all septic or damaged teeth removed from the neighborhood of the fracture some time previously A portion of a rib is then accurate ly fitted into the gap fastening it there either by wire tacks or by silver wire

It would seem that this transplant acts mainly as scaffold for the new hone forming cells, but a case reported by Albee would indicate that the transplants themselves have power of bone degeneration I II. Serter.

Latarjet, 4. The Working of Clearing Ambu hance (Le fonctionnement d'une ambulance) chier a 6 chi 166

The author gives very interesting particulars of the surrical work done in a neld ambulance during period of offensive To this ambulance service was assigned the work of receiving all the wounded from an army corps. During the 5 days of attack, 0.128 wounded were disposed of Of these Corr were al ghtly wounded, and 4.3 had more or less STAYE WOUDCLE.

Of the 1.0 alightly wounded, 616 were imme district dispatched to the dearing hospital. The remaining 4 355 were examined and had their

worderen autensta	1 DC90	*Officer	comprised

Thorax				354
Abdonsen				101
Upper limbs				1600
Lower limbs				1330
Multipl wound	4			46
Shock				QΙ

After the wounds were dressed these men were sent on t the clearing hospitals at the base. The 4,317 injuries of the seriously wounded were as

I OTTO M P	
Head	3 6
Neck	ŏδ
Thorax	531
Abdomes	±6 7
Upper limb	816
Lower limb	1443
Spine	1443 18
Genital organs	24
Multiple wounds	365
Gas intentention etc	41

Of these 4,117 108 died during the period within five days mostly a few hours after arrival and without intervention. Sixty three died while being conveyed from the field to the ambulance. The

total immediate mortality was 254

Of the 551 thorace wounds 176 were shell wounds, 132 bullet and o bomb wounds. Twenty three died between the first and third day from hemorrhage or shock 16 died from the fourth to twelfth day. Of the 26, abdominal wounds 124, were penetrating. Two hundred and fifty four of the wounded intransportable and inoperable were hospitalized on the spot. The others were dispatched to the cleaning base hospitals, either by saito or traff.

Hospitalization within a few hours of injury immediate large evacuation of wounds and evacuation only toward the interior when the patients are in a fair way to recover are the ends to be sought if lamentable consequences are to be avoided

SURGICAL PATHOLOGY

Bristol L. D: Free Tumor Diagnosis as a Function of State Public Health Laboratories. J 1 m If Ass 10 6 layi. 678

The results of investigation show that for pathologic examinations in state laboratories of the 48 states 24 have facilities for the diagnosis of suspected cancerous tissue either in their state public health laboratory or in some other state institution while 24 do not attempt such work.

Of the 24 states which have facilities for making tumor diagnoses 5 charge specified fees 6 harge all persons except indigents and 13 make no

charge in any case

From information available it seems that opin ions of authorities differ somewhat as to whether or not tumor diagnoses should be made free of charge either by state public health laboratories or other naturations as an important aid in the campaign against cancer.

The chief arguments received against the free diagnosis of tumor tissue in state laboratories are

as follows

- I Diagnosus of tissue for cancer is merely a private consultation and is not regard d as public health work
- 2 The plan would savor too much of state medicine
- 3 As a rule the appropriation for the state laboratory does not warrant the doing of more work and tumor diagnosis should not interfere with the diagnosis of the so-called communicable diseases
- 4. There is danger of spreading cancer-cells into other parts of the body by the excision of small specimens for diagnosis
- The following recommendations are submitted as worthy of consideration in the campaign against cancer
- r So far as consistent with local conditions facilities should be offered under public nuspices in each state for the diagnosis of tissue suspected

of being cancerous. Preferably these should be made free of charge.

2 The logical place for doing such work is the laboratory of the state health lepartment. It is not to be supposed that such work will be given prefer nee over other work now being done by these laboratories.

3 To cover this work in those states which have no such facilities additional money should be

appropriated

Judgment must always be used by surgeons in the removal of suspected cancerous tissue for diagnosis and the value of a mi-ruscopic diagnosis should appear to outweigh the risk involved before such a procedure is adopted

EDWARD L CORNELL

Birtch F W. A Group Study Plan for a Diagnostic Team Acting as a Laboratory for the Profes sion J is M is 19 6 1 i 67

St Luke's Hospital San Francisco is the only institution reported to have organized specialists to at as a laboratory for diagnost; purposes returning the patient after investigation to the referring physican with a protocol of the indiags and recommendations for the treatment of the case

This new era in medicine is very young the medical universities are not vet teaching this type of medicine they have in the evin accepted it and in fact them, is no definite instruction to be had on the subject. The method of group study now employed in hospitals by referring the patient from one department to another without joint discussion of cases by the heads of these departments is open to as severe criticism as that which Doctor Cabot applied to the methods of the general practitioners.

It has not been long realized that the three great classes of patients, the rich the poor and the middle class are receiving quite different medical attention. The rich man while he is able to pay for the services of a large number of high priced specialists presumably gets the best medical consideration but unfortunately the highly paid specialists are find viduals who are not organized and their work is not correlated consequently consultations are often perfunctory and unsatisfactory to both physician.

and patient

The disgnostic section of St Luke's Hospital San Francisco consists of ten men, each having special training along some particular line. The members of the profession refer obscure cases to this section for diagnosis. These patients are placed in the hospital for observation and each member of the diagnostic team makes an individual examination and a written report of his indings. At noon each day the team meets to discuss the cases. If the case is not clear at the first consultation further investigation is recommended and any new discoveries are reported the following day. This method of procedure is continued day after day until some con-fusion is reached. The physician

who referred the case is saked to be present at all of these consultations. Finally the patient is referred back and a written report of the findings and recommendations for t estiment are malled to the attending physician. Thus the specialists make of themselves a diagnostic laboratory

All of this work is being done by the diagnostic team for a fee commensurate with the patient income. The amount collected is not sufficient to pay for the time of the clinicians. However the good that is being accomplished by this method if study and the educational returns for each member of the team in daily discussion with his collectures

amply repays the clinicians.

The soccess of a pian of this kind depends, beliefly on the following coordinors. The diagnostic team must accept from the profession case I revestigation at a price consistent with the income of the patient cases should be examined by all the members of the team the results of their findings must be written the specialists meet in daily consultation over the cases, and Investigations continue until all possible evidence is discovered. The case is returned to the physician who sent it and a report is mailed, together with the conclusions and suggestions to treatment.

The results to be expected from such a scheme are these The general practitioner will gladly accept it the good influence of the fully physician will be preserved medical men in the community will take advantage of the daily discussions and gradually broaden their point of view of medicine than nethod of group study will maintain the advantages of precisions and do away to the advantages of Chinese properties of the community of the production are now being prepared for publication.

Binnia, J. F. The Rôle of the Sympathetic System in the Diagnosis of Abdominal Discuss. Am. J. M. Sc. 0, 6, 632.

The phenomenon of pain or tenderness in acute abdominal diseases occurring a situation different from the diseased organ, for example, the median line pain in early appendicitis—commonly spoken of as reflex pain—is explained by the author on the basis of development and physiology of the

sympathetic nerve supply of the region.

Reviewing the embryology of the abdominal
viscers, be points out the median position of organs
(and therefore of the never supplying them)
which later migrate t lateral positions, but their
nerve supply maintains the original median connections. The anatomy of the abdominal and
thoracic sympathetic system is reviewed in detail
and its connections with spinal nerves, pneumogastric, hieracle, etc. are recalled. Perfumblical
pain in the peritonities is explained through the disfibers to the doubleting. Here and naterio parietial
peritoneum as low as the untailities. The connections of the right representations of the infer through the dis-

nerves, through the disphragmatic piexus, explain right-rided abdominal pain in thoracic diseases, e.g. empyema or pneumonis.

Referred pain is due to the increased number of afternt impolaes from an irritated organ coming to the nerve-center which is unable to handle them in the normal way on the result is a radiation of other effectent impulses along the trunks of the sensory nerves, passing near the center giving rise to a sensation of pain at the nerve-endings. If a motor path is affected the result will be muscular rigidity

The phenomenon of crossed pain tenderness of the superficial sensory nerves, difference in protopathic and epicritic sensibility in abdominal inflammations with the esulting clinical signs, are de-

scribed in det il.

The author ducuses the more recent work by neurologists n the causes and nature of abdominal pan due to inmation distention, etc., and explains the origin of secondary pain or that arising through extension of the irritation beyond the origin first affected.

That renal pain is not middline is due to the lateral development of the hidney. Renal irritation as in size, therefore does not give rise to epigatric pain. The occurrence of atonic contraction of the anal sphaneter due to renal irritation and causing symptoms of intestinal obstruction is explained also the die of the sympathetic system and the phenomenon of radiation in genilicurinary organs, especially in prostated durases is el delater.

HORACE BRIEFY

Studdard, J. L., and Cutler E. C. Torula Infection in Man. Mesop ski of Rackfulle Institute for Med Research, 9 5, N 5 Jan., 31.

Two cases from the Cushing's clinic at the Peter Bent Brigham Hospital presented at utopay unusual lemons in the brain and meninges. histories and physical examinations included such signs of cerebral tumor as to indicate decompression or explorat ry operation, but the pathological examination in each case proved the complet absence of tumor Lexions were found, however which fully explained the clinical symptoms and physical siens. Enormous numbers of organisms having many point of resemblance to those of hinstomy cosis occurred in all of the lesions in such a manner as to leave no doubt of their casual relations. Certain differences from the usual descriptions of the organisms of the blastomycosis group and their lesions made a careful study necessary to determine the relations of the uthors cases,

Two problems which have received increasing attention in late years, without great propriet toward their solution, were thus brought to the anthor' notice by the study of the cases Le. the problem of cerebral psecodotumor and the problem of the relationships of the lower fung forming th group called blastomycosis. It seemed probable to the authors that their cases night throw light

upon both these questions.

In the study of the first problem that of pseudotumor cerebn, the literature furnished a considerable number of cases in which symptoms and signs of brain tumor existed for a short or long time with subsequent recovery or with indefinite autopsy findings.

In trying to solve the other problem, that of the relationship of the organisms of the blastomy costs group they studied the literature and made animal experiments. In their experiments they used pure cultures of three different organisms one isolated from a human case of cutaneous blastomycosts one from a human case of coccidioidal granuloma and one from Frothlogham's case of torula infection in a horse. Inoculations were made in various ways upon several species of laboratory animals and agglutination experiments done upon the infected snimils.

One of the problems in the authors work was the relationship of the organisms causing the diseases termed blastomycoses They have shown the confusion existing in textbooks where the various diseases are described as one disease or as different manifestations of the action of a single organism in different states. The study of the literature convinced them that coccidioidal granuloma was a disease distinct clinically pathologically and biologically from other diseases called blastomycosis Having decided that coccidioldal granuloma was a distinct disease, they turned their attention to the blastomycoses. They found in the literature two cases of skin and general infection produced by a true yeast with endospores in culture Both cases were observed by Buschke and appeared to be distinct from the American cutaneous disease. Froth ingham's discovery of torula infection in a horse indicated another type, but no such cases had been reported in human beings

The authors cases were distinct from the larger part of the reported cases of blastomy cosis in their clinical histories and pathology. It did not seem improbable to them that in the early study of blastomy costs such cases had been described, but their nature not recognized. They studied the original reports of all the cases of systemic blastomy cosis and found that nearly all the cases were similar so far as could be ascertained from the pinnted reports except those involving the brain. Among

these there were obvious differences. First there were six cases like the other systemic cases but in which the brain became involved as part of the general infection whi h always included skin manifestations and often bone lesions. The symptoma tology was not perceptibly influenced by the brain lesions The pathology of the brain lesions resem bled that of the other lesions Different from these were four cases in which there were no skip lesions but in which a general infection occurred with brain lesions which caused the predominating Pathologically the lesions were dis-5) mptoms tinct in many ways but principally in the extension by solution of tissue, the always chronic reaction, and the production of a gelatinous material in the lesions

Their first case was evidently identical with this latter group Their second case vas not fully identifiable by the study of the literature alone for the peculiar intracerebral lesions were not present and the parasites occurred in greater numbers of small forms. Such forms occurred in the meninges of the first ase but not in the intracerebral lesions and were not described in the literature. In the experimental meningitis in a mouse produced by the injection of a culture of the ventricular fluid from the second cale however large organisms were produced identical with those of the first case, and intracerebral lesions of the same type were seen in process of formation. Thus their two cases pro ed to be alike in origin. Frothingham's case of torula infection was evidently the type of infection of these cases. In their animal experiments with torula the authors found both forms of parasites present in the lesions in varying proportions accord ing to the extent and activity of the process. In a very active lesion enormous numbers of small organ isms similar to those of the second case occurred these were seen especially in the meningeal lesions In older lesions tending toward recovery or in those slowly progressing and in the higher animals the larger forms predominated. In sections of the original horse lesions small forms were entirely Their experiments resulted in the produc tion of all the variations in lesions and organisms seen in the cases The animal experiments thus provided the necessary steps for the clear correlation of all the human cases as cases of torula infection. George E. Beitey

GYNECOLOGY

UTERUS

Stein, A. The X Ray Treatment of Uterine Myomata; a Warning Based on a Study of the Literature. Mol Rac. 9 6 lxxnx 99

Stein sounds a warning to the enthusiast on the X-ray treatment of uterine myomata and has thor oughly rowiewed the literature of this subject cling numerous instances to substantiate his contention that the X-ray does not accomplish all that is claimed for th.

Since according to Klein, 7 7 per cent futerino my omate show malignant degeneration in some form. how is it to be determined whether one is radiating a malignant tumor or a simple myoma? As a matter of fact, the author continues, at the present at te of our radiological knowledge we have a perfect right to take for granted that the Ar ys may set up proliferative changes of a degenerative character in those areas f a radiated myoma which are not destroyed by the treatment. Furthermore, w men in the child-bearing age may have their functionating ovaries badly crippled or even destroyed, thus en dangering later offstring through changes of the germ plasm produced by extensive radiation. Ster ility is common following long exposure t the \ rays

The author calls attention to the difficulty in acfine author calls attention to the difficulty in accase of interestial preparacy with profess hemor operation for myome of the uterus. For inside the patient choice operation. She made an unevent ful recovery whereas, otherwise a rupture of her interstifial pregnancy might have mean; avided neath.

Injuries directly tracesible to the X-ray treatment of intra-abdominal lesions are practically on avoidable. Multiple peritoneal adhesions deep ulcers of the abdominal akin adersult changes of the perito connective tirsues untrature conditions of the bowel and bladder attrophy of the gastro-intestinal plands are conditions of lesser importance which may result from continued radiation

In conclusion the author says judiciously restrained the indications for the X-ray treatment of uterline myomata are very limited, including besides myomas patients who have reached the climaterie, those suffering in addition from diabetes, obesity advanced arteriosclerosis or hemophilia, in whom surpical interference involves serious danger t. life, HARVE S. BATTERES.

Crossen, II S. Choice of Operation in th. Various Classes of Cases of Retrodisplacement of the Uterns. J. Ha. St. M. Att. 9 6 mil, rfq.

The author has endeavored to make clear the method which should be employed to hold the uterus in anterior position.

A dependable presentation of this subject implies a careful consideration of the various operative measures devised and their adaptability to the correction of the pathologic condition present in different patients. There is considerable continuous at the present time and for the very good reason that there are certain factors in uterine support not yet fully understood even in physiologic conditions and much less in pathologic conditions.

less in pathologic conditions.

The following coording to the author may be

tak n as a safe working basis

1 Most of the symptoms in retrodusplacement of the uterus are du to complicating conditions. Therefore such conditions must be treated first and the teatment of the etrodisplacement will depend to a large extent upon the complications.

Normally the uterus is held in position by a combinati n of structures. Therefore, in any scheme of restoration, either this combination support must be restored or other structures utilized to home about a similar support.

3 Pelvic floor support is bsol ely necessary to the permanent correct on of any retrodisplacement.

4. When decided prolapse of the uterus can be excluded the problem, after treatment of the complications, resolves itself int maintaining the corpus uteri in the anterior position and the cervis in the posteri position of the petvis, with sufficient elevation of the uterus and adnexs t prevent dragging on hypersensitive attachments.

5 As this problem varies with the different pathological conditions present, it is advisable for purposes of study and comparison to group the cases into classes somewhat as follows:

- A Future pregnancy possible.
 - (r) Adnexa intact -tlasues freely movable.
 - Ovary and tube of one side removed.
 - Tube only removed.
 Ovary only removed.
 - (5) Diffuse tissue infiltration, fixing ligaments.
 - (6) Varicose veins of the broad lightments.
 (7) Cervix too far back
- B Pregnancy not possible
 - (1) Active uterus preserved () Senlle uterus preserved

6 For maintaining the corpus uteri in the anterior position there are a number of fairly satisfactory intra-abdominal methods which utilize one or more of the ligaments supporting the uterus.

7 In general, it may be stated that varianal operations for retrodisplacement is indicated in those cases where other deep varianal work is needed and lealons requiring abdominal section can be eliminated. HARVE B MATTERS

ADNEXAL AND PERIUTERINE CONDITIONS

Heineberg A.; Tubal Sterilization Pregnancy Following Bilateral Salpingectomy a Report of Two Cases and a Complete Review of the Literature. V F M J. 1916 cill 107

The author reports two cases of pregnancy following blateral salpingectomy where the tubal stumps were merely ligated. With this report he presents a careful review of the subject in its surgical phase discussing the various surgical procedures that have been developed.

He offers the following conclusions

I There is no method of tubal sternization which affords absolute security against conception

which affords absolute security against conception.

2 Simple ligation of the fallopian tubes with either single or double ligatures has been followed by the largest number of reported failures.

3 Excison of a wedge-shaped section from each cornu of the uterus, followed by careful closure of the opening with musculomuscular and seroserous sutures has yielded better results than any other method

4. In the light of our present knowledge it seems unwise to advocate any other method than cornual resection. The conclusions are in accord with those arrived at in previous reviews of this subject.

CAREY CURRENTON.

Long J W Shirring the Round Ligaments. 1. Swg Phila. 1916 hill 600

To the multitude of operations already devised for the correction of backward displacement of the uterus the author adds another for which he claims simplicity and efficiency. It consists in grasping the round bgament near its middle with a forceps and making traction upon the distal portion While this tension is held a round needle armed with linen or silk, is thrust through the ligament close to the pelvic brim just as it leaves the inguinal The needle is then put through the ligament by an over and-over stitch about every quarter of an inch until a sufficient amount of the ligature to insure a proper degree of shortening has been in cluded the last puncture of the needle usually pass ing through that portion which has been traumatized by the forceps. By pulling the two ends of the lig ature together the ligament is shirred and the nec essary shortening produced. In addition to this the author has found that traction on the suture de velops a small mesoligament which springs from the pelvic wall. This piece of peritoncum may be well utilized to cover over the shirred portion of the lig ament. The same suture may be used for the en tire operation. GATEWOOD

EXTERNAL GENITALIA

Gittings, J. C., Hamill S. M., and others: A Report of the Committee on Vaginitis. A ch. Pedial. 916 xxxiii, 361

This committee appointed to investigate the subject of vaginitis in infants and young girls

conducted a very thorough investigation. A questionnaire was sent to various institutions canng for female children and to a large number of pedia trivans. With these replies as a basis they formulated the following set of resolution.

1 That cities be required to provide adequate hospital and dispensary facilities for the care and treatment of children having variaties

2 That matrons be placed in charge of the girls toilet rooms in public schools

3 That toilet seats embodying the principle of the U shape be used in all schools and that the toilets be of proper height for different ages.

4 That city and state laboratories be empowered and equipped to make bacteriologic examinations for physicians when patients cannot afford to pay a private laboratory fee

5 That educational literature on the subject of vaginitis be prepared and distributed to mothers through the medium of physicians heaptids dispensaries health centers municipal and visiting musics.

6 That asylums for children and day nurseries be heensed and that the heense be not granted unless hist the institution has adequate facilities for the recognition of gonococcus againtis, and second that the institution circlude children having this disease if they annot be properly isolated.

7 That separate wards be maintained in hospitals for the treatment of children with vaginitis

who are also suffering from other diseases.

8 That microscopic examinations of smears be mad before admission to the general wards of the hospital. In securing material for the smears extreme care should be taken to observe rigid supptic precutions.

g That observation wards be provided.

To That individual synnges bed pans, catheters clinical thermometers thermometer lubricant wash basins soap powder wash cloths and towels be provided

11 That single service diapers be used (at least for girls) or that diapers be sterilised in an autoclave at 15 pounds pressure for five minutes

12 That nurses be required to make daily in spection of the vulva of each at the time of bathing and to report immediately the presence of the slightest suggestion of a vaginal discharge.

13 That low toilets be provided and equipped with seats embodying the principle of the U shape

14 That for routine purposes, the sprsy be used in place of tub-baths for the bathing of young girls and that older gurls be sponged in bed

15 That nurse receive special instruction as to the nature of vagnitis the case with which it is transmitted the methods of preventing its spread and the necessity for rigid aseptic surgical technique in its handling and treatment

16 That a dispensary with special facilities for the treatment of gonococcus vaginitis be provided

17 That nursing care and supervision be given in the home

18. That mothers be instructed as to the dangers of vaginitia, the manner in which it is transmitted, the best method of protecting other children, and the necessity of projoured becryation

ro. That all cases of vaginitis under observation be voluntarily reported to the local health officer in states or cities where no legal requirement are in force. Edward L. Cosserr.

MISCRILATIOUS

Watkins, T. J. Disgnosis in Gymecology Charge M. Reserver 9 6, xxxvvii, 339.

An analyzis of abdominal pelpation shows that it is always relative, that the findings are estimated by comparing the resistance to pressure over various areas of tissues or organs. By comparison only can a very soft pregnant uterus, a distended bladder or cyst with findid wall be at times detected by papinton. The palpation hould alw ys be light, as

from pressure lessess the tartile sense, causes pain and excites rigidity. Observation of the facul expresion is of great value when pulpating for tenderness. The technique of kidney pulpat on consist. I the

one of delicate withratory pulpation, so has in a ployed in Umanual examination of the uterus and ovaries. One hand is placed just be! when his posteriorly and presen the kidney gently forward with the other hand delicate withratory con ter pressure is made anteriorly over the region of the kidney.

Greater tenderness over the region of the appendix than over the corresponding region on the positie side is disgnostic of chrond appendix to other demonstratible pathology being criticaled. Absence of tenderness does not exclude appendix in a gross pathologic changes in the appendix re frequently found in the basence of t inderness Artophic changes (appendixits oblitzers in 5 cm. 3 are accompanied by increased tenderness in about 30 per cent of cases. Palpation over the region of the appendix in all graceological patients is highly important, as experience has demonstrated that the appendix in diseased in a very large percentage of cases with extendive policy gathology.

Valuable Information is obtained from vaginal impection and pacipation. Urethrocale is frequently not detected and the method of diagnosis is not generally known. Ureth ocale is essentially a down ward and not backward displacement of the urethra. Urethrocale is detected by pressing the urethra great toward the cervits, and the distance it can be so displaced represents the extent of the leajon, as it is normally quite fixed.

The position of the uterus can often be determined by the appearance of the cervix. When the anterior lip of the cervix is much thicker or longer than the posterior the uterus is almost invariably in anterior position. The same rule applies to the posterior lip

of the cervix.

Palpation of the aterosacral ligaments for tender pess is important as it often helps determine the degree of pathology of a retroposed uterus A most difficult class of synecological patients to diagnose are those with pelvic pela without well defined pathology. Mistakes are commonly made in such cases, as the pain may be due to pathologic states that cannot be detected on pelvic examination, or the petient may have or compalin of pain without the presence of pathology in the pelvic organs. It has been found that the pain from decisions is chiefly due to traction upon the period period of the pelvic pelvic period of the pelvic pelvic

The I we mortality of abdominal section tempts the surgeon t operate for pelve unproons without making a careful diagnosis, and for pelve appropriate without demonstrable pathology. Surgery has developed beyond the time when the results of operations should be based upon mortality. The real test of modern fiscient surgery in morbidity.

The is onsid able danger of occasionally mistaking a large corpus luteum for a small ovarian cyat and of thus subjecting the potient to an unnecessary operation. The corosis luteum at times attains a size two or three in hes in dismeter due to harmorrhage or ordens about the gland. On confolded palpation it is impossible to duti mish it small ovarien neop! m The diagnosis should be made by constantly keeping in mind the possibility of a large corpus luteum in the diagnosis of all am Il ov rian tumors and keeping them under observation a sufficient length of time to allow absorption in use of corpus luteum. A lapse of ne month is probably I ag enough to establish a dif ferential diagnosis EDWARD L. CORNELL

Bello, A. Menstrual Fistula of the Abdomen (Fistula manurual del abdomen) Rev essec mell Augent 9 6 km.

The case eported by the uthor occurred in a woman of so showing ympotoms of tertilary styphila. The uterus was ant slexed with both annexes enlarged and the ut rus between them instanced and painful and showing a prominence in the left likes focus without any modification of the white. Exploration of the sound disclosed nothing of importing the state of the state of

The fistula persisted in spate of all attempts at treatment, and haprateony was done. The epi ploon and intestinal loops were adherent to the left uterts and naner. The ut rus was fibrors and twice the usual size and dherent to the bladder The right anner was exist. The tube of the left anner was largely cyalle in the ampullar region. The first part of the tube led to a fixtule which was located in the abdominal wall at the left of the me dian light.

A subtotal hysterectomy was done with ablation of both annexes. A portion of the epipioon was

resected and the fistulous tract closed by sutures. 11 L. BRENYAN Recovery followed

Stevens T G: Adenomyoma of the Rectoraginal Septum Proc Roy Soc Med 916 lx Obst & Gynes Sed 1

The author refers to cases described by Lockyer Spencer Leitch Bland Sutton, Gough and Stewart and to his own case previously demonstrated in 1900

During the preceding eighteen months he has had under his care five more cases These are tabulated in detail and illustrated In the fourth of these cases the anterior rectal wall had been so involved as to be drawn up in a double fold without however invading the rectal mucosa. In this case there was also present a cyst of the vaginal wall undoubtedly of Gartnerian origin.

Stevens notes that the symptoms varied case they were menorrhagia and dysmenorrhora in two cases sterility was the only complaint in the other three bleeding was the chief symptom due in one case to fibroids in the body of the uterus in an other to chronic metritis and in the last to some un explained general condition associated with the men opause.

The growths are all situated in the loose connec tive tissue above the posterior vaginal fornix, bound ed antenorly by the back of the cervix, postenorly by the rectum, above by the perstoneum sent hard nodular masses fixed to the back of the cervix and movable with it. They are not tender to the touch and cause no pain. The rectal wall may be involved but the rectal mucosa never

Microscopically these growths show precisely the same structure as a diffuse adenomyoma of the endometrium but as a rule the gland tubules surrounded by endometrial stroma are few in number. The tubules are often dilated and cystic, not infrequent ly containing blood or blood pigment The sur rounding stroma is composed of cell elements exactly like the stroms of the endometrium. The fibromus cular part of the tumor is clearly a definite new growth Although there is no capsule the arrange ment of the fibromuscular tissue is such that the growth is quite sharply marked off from the uterine muscle coats. There is perhaps more fibrous and less muscle tissue in the growth than in the uterine wall. In none of the specimens was anything found to suggest an inflammatory lesion

The author discusses the various theories regard ing the origin of these tumors and holds as untenable his original view that they are derived from wolffian remnants. The possibility that they are derived from the muellerian ducts at the place where the fused ducts join the solid mass of cells from which the vagina is developed cannot be disproved.

CARRY CULDERTSON

Montmari E.: The Pathogenesis and Treatment of Genitul Prolapse (Sulla patogenesi e ulla cura del prolasso ge Itale) CIn k 9 6 vri 223

The author passes in review and criticises the various methods in vogue for the treatment of genital prolapse. He does not believe that vaginal or abdominal hysterectomy can ever be considered an ideal method but only a procedure of necessity masmuch as such operations produce a grave and irreparable mutilation hence the method should not be used on a young woman with a normal

Treatments limited to the vagina, such as col porraphy and similar operations are insufficient and interfere with colitus while they do not obviate the anatomopathologic alterations which were the

principal cause of the genital prolapse

The author insists that genital prolapse is chiefly due to inequality between the resistance of the peritoneum and endo-abdominal pressure such in equality being determined either by a congenital or an acquired weakening of the support and stability of the uterus and especially of the soft framer ork forming the pelvic floor. As a surgical procedure the author considers the operation devised by Ruggi to be the most efficacious and rational for the treatment of total prolapse in women within the active period of sexual life

The main points in Ruggi's operation are as follows

A cu gular incision above the normal position of the fornices two incisions perpendicular to this on the two sides of the anterior vaginal column these incisions being turned off at the ends. Three flaps of mucosa are thus formed the central from the an terior vaginal column and two quadrilateral side The neck of the uterus is drawn out and isolated. The two lower thirds of the lateral walls of the uterus are sutured with catgut to the base of the broad ligaments

2 Obliteration of the ureterovesical and ureterorectal cavities suturing the uterine fundus with fine catgut to the peritoneal sac which covers the posterior face of the bladder replacing the uterus. Douglas a sac is autured to the uterine fundus poeteriorly supervaginal supputation of the neck of the

I osteriorly the sectioned vaginal mucosa is su tured to the posterior half of the stump of the neck in such a manner that a perfect adaptation is made

between the vaginal and utenne mucosx.

In front the vaginal column previously isolated is deprived of its superficial mucosa and shortened at its free extremity so that there remains only a strip of solid submucous tissue which is sutured to the enterior edge of the sectioned neck. This submucous strip is then covered by the two quadri lateral flaps previously mentioned The operation is completed by Lawson-Taits colpoperineor rhaphy

The advantages claimed for this operation are

Consolidation of the musculo-aponeurotic ring which includes within it the isthmus of the uterus. and high fixation of the uterus in approximately its normal position.

2 Aboution of pathologic perstoneal formations constituted by the uteroves cal and uterorectal sacs.

3 Reduction of the weight and volume I the uterus by amoutation of the neck.

4. Narrowing of the lumen of the vaginal canal and of the vulvar orifice cure of cystocele and retrocele and consolidation of the perincal floor 5. Preservation of the integrity of sexual function.

The author reports eight cases very successfully treated according to this method and in at least one case it was followed by normal pregnancy and parturition. W A. BECKEAR

Housey A. A. Operating During the Puerperlum for Curs of Old Lacerations of the Gervix and Perinsum. Am J Ohn V Y pro band 14.

The author reports 4 cases in which Stuart and himself had operated for cure of old incerations of the cervix and perineum during the puerperium. He does not contend that this time of operating is more favorable than other times but thinks that for some of the poor patients in the maternity wards there may be some real gain by operating at this time, since so many of these patients will not re turn to the hospital even though they are more or less invalided because of their lacerations.

In 20 of the cases operated upon the recent 1 bor had been conducted under normal conditions in the delivery room. In two cases labor began outsid the hospital and terminated in the receiving ward without preparation for delivery. One case was admitted with a transverse present tion with prolapse of the cord and arm after unsuccessful ttempts at version by the family physician. Placenta pracvia complicated tw cases. In two cases labor was induced with a bougle. Labor was terminated twice with podalic version and twice by forcers.

The lesions found in these cases were 3 old lac erations, o old and new lacerations of the permeum s old lacerations, and 5 old and new lacerations of the cervix.

The cervical lacerations ranged from moderate

single t deep multiple. The lacerations of the perineum were incomplete in 38 cases and complete in a One case was complicated by a cyst of Bar tholin a grand and hemorrhoids.

The time selected for operation was from one to filteen days post-partum. Five cases were operated upon twenty four hours after delivery CLICS forty-eight hours after delivery. In o cases, the operation was done between the third and seventh days, and in a cases between the seventh and fif teenth days post-partum. The post-operative course was entirely normal in 35 of 40 cases and 5 had a little temperature.

In an of so cases of trachelogrhaphy the cervix is

recorded as healed. Partial union occurred in 3 cases and non-union in one.

Good union was secured in the perineum in 32 cases, and partial union in six cases non-union is recorded in one case. The condition of the pelvic organs on discharge was normal in 34 cases, while retroversion of the nterus was noted in 6 cases.

The presence of lochia did not seem to have any unfavorable effect upon bealing. The post-opera tive care did not differ from that of cases repaired C H. DAVIS. after recent injuries.

Healy W P Sterility in the Female. Mrd Rec p16, lexxiv oca

Sterility in the female may be due to pathological conditions grouped as follows (1) malformations, (s) inflammations and infections, (3) injuries, and

(4) tamors.

Relative terility cases in the fourth group are due t fibroids of the uterus or in the third group there may be miscarriages as a result of uterine displace ments or traumatic lesions of the pelvic organs foll wing previous pregnancies.

The gonococcus is chiefly responsible for sterility to inflammations. Practically all cases of absolute sterility belong etiologically in the first and second groups. Lack of complete development of the oterus is the most frequent factor in the first group. On this the clinical findings fall into three groups (1) small poorly developed sterus with scanty mensure tion, (2) small uterus with anteflexion a normal period, and dysmenorrhom, (1) a normal sized uterus with long conical cervix. stenous of the cervical canal menorrhagia, and

dysmenorrhoea. Any on of the above groups may be complicated by retroversion. Apparently nor

mai organs in apparently healthy sterils women are

found. These cases often have ex-essively acid vaginal secretion. Apparently normal cases are benefited by saline douches at bed time and a restriction of intercourse. Groups 1 and 2 should have dilatation, curettage, and stem pessary. Group 3 can be helped by dilatation, curettage, and the Dudley operation on

the cervix. Retroversions should be corrected by pessaries or

operation. Sterllity due to goodriberal infection is least satisfactory to treat. Those cases in which no palpable lesions of the adnexe exist should have dilatation curettoge and saline douches. Failing this an exploratory laporatomy should be done with proper care of any adhesions found.

Gonorrhotal cases with polpable lesions recuire curettage and plastic surgery on tubes.

W F Hewitt

OBSTETRICS

PREGNANCY AND ITS COMPLICATIONS

Costa R. Treatment of Extra uterine Pregnancy in the Advanced Periods (La terapia della gra danza extrauterina nel periodi litrat) Gesdesped d. Milano 1016 [VVVVII. 20

The author believes that after the sixth month active intervention is necessary. If the focus is dead operation can be delayed for about a week if the condition of the mother permits it. If the factus is alive the termination of the pregnancy can be awaited.

Intervention can be made vagually or abdomin ally In the former the colpotomy incision must be sufficient to allow free passage of the head. Introduction of the hand or external maneuver are generally to be discountenanced and it is best to

allow spontaneous placental elimination.

Abdominal extraction is indicated only wh in the conditions are unfavorable for vaginal extraction Median incision is the rule but when the sac is developed in the large ligament the Pfannenstiel incision is resorted to Difficulties in abdominal extraction are ascribable not to the fectus but to the treatment of the annexes. These may be left in tact or they may be partially or totally removed. The latter is the ideal way In leaving the append ages behind there should be partial or complete closure of the abdomen. Partial closure finds its indications in septic or suspected cases when the sac and the placenta are firmly adherent or danger ously implanted on other organs, such as the liver bile-ducts etc or when the placenta is very difficult to remove. In this case the technique is reduced to the opening of the abdomen and the sac, the extrac tion of the foctus tamponing marsupialization of the sac, and partial abdominal closure. Total removal of the ovarian tissues is the ideal procedure and the most correct surgical method.

W A. Bremman

Arnold J O: Some Practical Points in the Treat ment of Eclampela Ther p Ga 1916 1, 381

Amold believes that a judicious combination of the Stroganoff or conservative method with some of the best of the more radical measures is in most cases productive of more satisfactory results than an attempt to follow either school alone. The Stroganoff method in several of the large European maternity hospitals has reduced the mortality in eclampia from 20 per cent or more to 8 per cent or less 1 tis, consequently, the duty of obsectricians to gave serious consideration to such a method and so far as possible to adopt it in practice for no other treatment has ever given half so low a death rate

Most American and English obstetriciens how ever believe that the uterus should be empitted whenever one or more convulsions have occurred Consequently the author feels that after the convulsions have been controlled by the Stroganoff method it is logical to terminate pregnancy by whatever procedure will give the least shock to the patient

Arnold s plan of treatment is in brief

r Chloroform if necessary in the smallest possible quantity that will enable one to give the first dose of morphine without disturbing the patient

- The first dose of morphine at least half a grain to be repeated in two hours or as soon and as often as is necessary to control the convulsions.

 Bleeding as early in the attack as possible to
- the extent of from 12 to 24 ounces sufficient to effect lowering of the blood pressure
- 4 After cleansing the lower bowel, the administration by rectal seepage of a solution containing 1 or 2 drams of sodium bromide and 2 or 3 drams of sodium carbonate to a quart of normal saline as rapidly and constantly as it may be absorbed. In case of rectal intolerance he advises a solution of 2 drams of bicarbonate of soda to the pint of normal saline by hypodermodysis.
- 5 In cases before the eighth month after two or three convulsions induce labor After the eighth month terminate pregnancy by the most appropriate method.
- 6 With the possible exception of water no drugs or food are to be given by mouth until long after the convulsions have ceased
- The author reports 17 cases with a mortality of 5. He states that in every case in which treatment was carried out efficiently from the start the results were good. Some of the consultation cases seen late were morbiund and could not have been saved by any method of treatment. F. C. Isviro

Boyd G M The Indications for Casarean Section Am J Obst N Y 916 lexili 650

The author believes that the low maternal mor tality from execution section within recent years has led to an almost reckless broadening of the in dications until at the present time this operation is performed far too frequently. He considers pelvic deformity in which the true conjugate is less than 7 s.cm. and pelvic obstruction as the only definite indications. As long as the etiology of eclampia is obscure, its treatment by means of cesarean section is questionable, in rare cases he thinks it worthy of consideration but considers manual dilatation and rupture of the membranes, followed by

version or forceps, the better method of treatment for most case. It is to be considered in some cases of placents pravia and is the method of greatest safety for central placents pravia. He questions certain an-called indications as face, brow occipations as called indications as face, brow occipations positions, profilis, and primary inertia. He utges that the test of labor should be given the patient in all cases in which the indications real relative. C. II. P. ovas

Costa, N. P. Segmental Constroin Operation (Cost rea segmentaria) Semaine mid., 9 6 xxiii, 55

Under this title are included those procedures which involve the lower segment in contradisting tion to the classical createrns operation which always involves the uterine body. The group includes suprasymphyseal ingulant, cervical posterior sections and laparocolpohysterotomy.

The author refers t th various procedures since Jog of Leipsig in 180; and Onander shout the same time first exposed their technique. Ritgen par the extraperitoneal method into practice in 8: Thomas, of New York in 1850 revived the technique of Ritge and the statistics published later by him and his followers showed a maternal and fertal mortality of 5 and 4:18, per cent respectively which was no higher than the mortality from the classic operations.

The third country is the methods were multiplied and according to Holespid and Franch there
were more than the seventeer distinct procious. The author numerics each (these methords which he states may be arranged in two greatgroups, the extrapertioneal and the transpersioneal.
The first was founded on anat mu principles, the
transpersioneal method arising as a excassly due
more or lens to the difficulties of techn qui which in
the majority of cases sufficed to empletely nullify
the object of the Intervention. Franch originally
followed the artrapertioneal rout by twigs to the
difficulties encountered was the first to try the transpersitoreal and published his first seven cases in
1904. His procedure was later moditied by Selheim, Latake and others.

Accidents are more merous by the e traperi toneal route owing t the anaturated difficulties and conditions artising which cannot be foreseen. The most common accident is peritoused i jury and coording to the statistics of Jeannia and Schau te the peritousum was opened in bout teachy per cent of the cases. Nowvis statistics sho ed 3.5 per cent, but Latako and Dodrelan by their proceed upon the control of the cases. In the control of the cases, the control of the cases are controlled to the figure to a sand 7 per cent percent level.

The next most frequent accident was vessel upture which occurred in about 3 per cent of the cases. These and other lesser ceddent are, however reduced to minimum by the transpert need method. Sometimes the terine muscle is lacerated or torn. As late accident fination of the uterus to the abdominal cleaturis has been observed, and this facilitates retroflection. Such addressness, as:

cording to Wiebel are met with in 25 per cent of the cases but they rarely cause a premature delivery or a grave dystocia.

The principal indication for a segmental casarean

operatio is in a case where the classic operation is contra indicated, i. a case with infection. This indication, however has not borne the brunt of criticism because the transpertoneal procedure with its provisory sutures is not capable of hinder ing cont mination of the peritonical carity or preventing the evolution of f tall peritonlits.

Seltheim from his studies considered that segmental cassarean section was the nip treatment in placent pravia and in alx cases so treated by him and one by Henkel there were no deaths.

The general opinion bowever pregrat to be that this procedure cannot compare with pure obstatrical procedures o with the classical censurean section recept in very special cases or in case of complete dystocia. Any other condition which contra-ladicate the classic operation are indications for the segment at 1c., threatened rupture of the iterius r incomplete rupture of the lower segment pail on many tuberculosis, mealinglits, pelvic it more etc.

The unto believes that owing n the one hand to the great number f cases of subsequent rupture in the scar and the adherence of the terms to the botonian awal and organs in the classic crastran, and on the other hand to the absence of such complications and more especially the firmners of the segmental cleartrix, this intervention should be segmental cleartrix, this intervention should be studied further and an endeavor made to give it broader locitations. Co cerning the maternal and forcal moretality and m riddity the author refers to Jeantinn a statistic, published in 1000, which gave cases with global m radiity of 7,3 per cent. Eliminating eight deaths due to infection reduces the figure to 5,38 per cent. Latrico statistics,

2.88 per ent Weibels 3 per cent. Jeaninn statuttes showed more or lens grave post-operative compilications in about 30 per cent of cases. Not alma a per cent. Fortal mortality varies according to the dufferent satisfact from 1.3 1.36 per ce inditing deaths prior to interven. 1 n. Asphyranted botths compare favorably with the classical operation.

omitti g infect re deaths, gave an operatory mortal

ity of 4 per cent, Nouvian s 3 6 per cent Bumm s

According to the statistics the segmentary cenarian operation has an advantage of more than a percent we the classical operation. Among the principal objections to the classical operation, as pointed out by Seitheim, are harmorizage interestinal leal in a fullity of infection of abdominal cavity by the introduction of ambiotic fluid and blood epipiote adherences danger of cleating triping in later labors frequency of abdominal herbig, etc.

Schauta has pointed out that mori of these are merely the result of faulty technique and thinks that segmental casarean section lacks the advantages chilmed for it and that the probability of infect tion is greater—Although episions are divided the author concludes that dominant opinion at present is for uncomplicated cases the classical operation for suspicious cases the segmentary and for manifestly infective cases a Porro or uter parietal hitula operation. W.A. Bar. W.A. Bar.

Beach R. M: The Management of O arian Tumors Complicating Pregnancy Labor and the Puerperlum. As: J. Obst. N. Y. . , C. I. viii.

From the frequency of ovarian tumors and their infrequency as a complication of pregnan v the author reasons that these tumors do actually rie vent conception. A thorough routine examination of all antepartum cases as early in pregnan v a possible will do much to eliminate the danger of the situation. Beach finds that the main complication torsion rupture and suppuration, or ur in 510 so per cent of the cases associated with the pregnant or progressed state.

The author believes that ovarian tumors discovered during the first half of pregnancy—hould be removed by ovariotomy before the secord half of pregnancy. If the tumor is discovered during the second half of pregnancy it should be removed it of considerable size since the excessive distent in of the abdomen might tend to interrupt pregnan v. A waiting policy should, however be chosen for other cases, such as dermoids broad legament tu mors pelvic bound tumors and bilateral tumors in the childless woman.

Non-obstructing tumors discovered during labor should not be operated upon if labor is progre ing well. Obstetric manipulations should be limited and labor made as easy as possible

Obstructive tumors seen during labor are considered under three headings. (1) Clean cases seen early in labor may be treated by posture and reportion, crearest section plus ovanotomy or waiting and! full dilatation of the cervis, which is dangerous owing to the possibility of rupturing the cyst. (2) Clean cases at the end of the initial stage should be operated upon as that method gives the best in sight into the condution present. (3) Infected cases seen late in labor must be operated upon at once. Cases that pass through labor should be operated upon during the puerperum.

CHDV

Danforth W. C. Pyelitis of Pregnancy with Especial Relation to Its Etiology S & G Obi 9 6 xxii, 23

The author made simple cultures on Flood erum of the unne of so pregnant women. In only two of these were colon bacill found. The remainder showed a growth of staphylocxcus. A further series of 14 was much mor carefully studied the unnes being cultured in sgar plates to which human saciets sluid had been added in magar shake cultures and in anaerobic tubes of agar to which had been added human ascites fluid and goats blood. None of this series showed colon bacilli. One showed a

pseudodiphtheria bacillus one an unrecognized sporetorning bacillus. With the exception of a few which were entirely sterile the remainder showed staphylo

An iservation is included upon a case in which the ureter were aftee einz dio releave distention of the right like inc. Plan The a heiter would not feel up the littener ail. Upon placing the patient upon the littener ail. Upon placing the patient upon the littener ail. Upon placing the patient was right in the ure et the cacheter passed up the ureter vice readil and urine flowed rapidly from the catheter little is as uined therefore that obstruction of a mechanical character in the caused by the ure vice a long backling the research would be used. As long backling the research would then up the assumes that the intest in its in the major into its above to the contraction.

A to treatment in addition to po tural methods the use I the ureteral catheter is urged privious to diving upon empty ing the uterus. The author bilieves that a con iderable number of cases may be rely ed by this means. Nephrotomy and nephrectomy are discussed.

Norris, C. C. Pregnancy in the Tuberculous. 4m

f Ob t \ 1 = 0 6 l viii 99

The study of this subject has led the author to belie e that as a general rule pregnancy and as pecially the puerperium exerts an unfavorable in fluence upon the course of tuberculosis. Whether the normal pre-mant woman is more susceptible to infect in by the tubercle bacilli is still an open question. It is certain that a definite proportion of omen apparently contract the disease either durin pregnancy or the puerperium. This is particularly true of the wives of tuberculous men living am it unlivances surroundings.

The combined results of fourteen observers show that the a erage infain mortal it in a large sense of cases was 58 % per cent. Armand Delille studied a series of 8 children born or living in 175 families one or more members of a hick were tuber culou. Of these children 373 were placed in the country and did well 306 eren tremoved from their infectious surroundings, and of these 238 developed tuberful 33.

Apart from the exacerbation of the pulmonary condition hich occurs so often during pregnancy it seems that these patients are more subject to the various obstetrical complications than normal individuals

Mbeck of Norway treated 16 patients in a private santanium, set 6 ded vithin fifteen months. Lasen Moeller reports that death or aggravation oc curred in 50 per cent of the spatients treated in private san tanium. Ebeler from a study of 32 cases advises the immediate emptying of the uterus in any month of premaney. Larry reports that in a serie of 38 cases all of the se cretype to per cent died within two months after labor. Bacon estimates that 33 per cent of tuberculous wom in die in less than one year after labor.

Practically all authorities recognize the gravity of laryngeal tuberculosis. Feliner in a series of 180 cases had a maternal mortality of 44 per cent benstine collected 23 cases of laryngeal tuberculoses from the literature 200 or 86 per cent of whom died during pregnancy, labor o soon after and Raspine emphasizes the ill effects of this condition. The death-rate among the infants of these patients was about 60 per cent Imboler reports a fortal mortallty of from 86 to 00 per cent when the mother has a laryngeal involvement. Knettner oo per cent. and several others give similar figures.

Tuberculous women should not nurse their chil dren, except in exceptional circumstances, for the mother's sake and because of the dangers to the

child.

Unfortunately despite the most painstaking studies, it cannot be determined with certainty which women will bear pregnancy and the puer The salest perfum well, and which will fare badly plan for the tuberculous woman is t avoid conception. In those exceptional cases in which conception has been countenanced, strict hygienic measures must be enforced and the woman kept under close observation and examined at frequent intervals by the experienced internist

In the early months of pregnancy with a rapidly advancing pulmonary lesion, there can be no question but that the induction of abortion should be performed without loss of time and this is also true if laryngeal involvement occurs. On the other hand, given a similar case in the late months of pregnancy little can be gained by the induction of premature labor The author believes that in the presence of an extensive lesion, even in the quiescent period or even of a small active lealon, or any laryngeal lealon the uterus should be emptied at once. The longer

a lesion has been inactive the better the prognosis, as a general rule.

The combined statistics of 1 observers, comprising nearly 1 000 cases of intervention within the first four months indicate that 77 per cent of the women were benefited by emptying the uterus, the percent age varying from so to 97 per cent. The author believes that the wise obstetrician will familiarise himself with the results obtained by others, and that be will individualize his cases, and empty the uterus only when it is necessary but that he will not allow his natural repugnance t the performance of this operation to influence him to the detriment of his patient, if after consultation it seems advisable. C. IL DAVIS.

Vantrin The False Appendicites of Fregnancy (Les i mass appendicites de la grossesse) d a de grade, et d'obsi p 6 xill, 77

The author reports five cases in which there was a diagnosis of appendicitis, all the clinical signs apparently being precise and conclusive, but which proved wrong on intervention.

In the first case a gangrenous diverticulum show ing all the symptoms of ppendicitle called for urgent operation. The opendix was found absolutely normal. In two other cases the trouble was found to be due to a suppurated dermoid ovarian cyst. The fourth case was very interesting. It presented all the classical signs of modden pains in the right lower abdomen, particularly located over Mc Burney a point. Intervention, however showed the carcum and appendix to be healthy with a hamatic collection above them which extended into the illac forms as far as the uterino cornus behind and the broad ligament below. A disrupted inpullar preg nancy on the right tube was found coincident with an imal uterine pregnancy which continued to term.

The tifth was a post partum case which was found t be due to the twisted pedicl of a partially suppurated ovarian cyst the symptoms of which simu

lated appendicitus W A. BREDGEAK

LABOR AND ITS COMPLICATIONS

Grad, H d, H. Fortal Dy tocia and Commrean Section. Vol. Rec. 9 6 lextus 1 37

The author reviews the various forms of treat ment of fortal dystocia with a plea for the more frequent performance of cresarean section for this complicatio f labor

The various forms of feetal dystocia are classified as follows

Fortal dystocia from faulty attitude (1) excessive flexic of the head, Roderer' obliquity () Bregma presentation, incomplete flexion (3) brow presentation (4) face presentation (5) presentation of ant rior parietal bone or ear Naegele bliquity (6) presentation of posterior parietal bone or ear Litamann a bliquity

2 Fortal dystocia from faulty presentation (1) pelvic presentation (2) aboulder presentation

s. Fortal dystocia from faulty position persistent occipitoposterior position () persistent mentoposterior position

- 4. Fortal dystocia from general fortal conditions) multiple or compound presentation (a) multiple birth (3) malformation (4) deformities (5) anomalica.
 - 5. Oversize of fortus.
 6. Oversize of bead.

7 Premature ossufication of head

Congenital hydrocephains. In many cases of delayed labor due to fortal dyatocta hast is unnecessary, a quick and immature co clusion should be avoided. The history of the case must be fully considered whether the labor is at term or ove due the duration and progress of labor the nature of the uterine contractions, especially as to the efficiency the general condition of the mother the condition of the amniotic me, the condition of the fortus, and of the uterus and the condition of the rectam and bladder. Full informs tion as to the above points will serve to assist in determining the proper procedure to follow Having obtained a full history of the case a careful exam instion of the moths, and fortus should be made.

Under full anresthests the whole hand if necessary should be passed into the vagina and an effort made to correct any faulty attitude or position and if possible to engage the head in the pelvis. By allowing labor to continue many faults will be spon taneously corrected by the forces of nature or rendered amenable to an easy forceps clear by

Under operative treatment the author diare gards embryotomy upon the living child publictomy

is not considered

The high forceps operation is regarded as a dan gerous procedure for both mother and baby and justifiable only under exceptional circumstances. The high feetal mortality and considerable maternal mortidity of version should cause it to be regarded as a formidable procedure.

For clean cases ensure an section is the ideal mode of delivery yet its dangers shock hemorrhage and sepais must be weighed against the dangers and limitations of the alternative operations

PHILIP F WILLIAMS

Telfair J II Rupture of the Uterus During Labor Am J Obst N Y 0 6 1 vm. 655

The author gives a brief discussion of this subject reviewing some of the recent literature and showing that one of the more common causes working to in crease this condition at the present time is the reckless use of putitirin in the general practif of obstetrics. He reports two cases of rupture of the uterus during labor the brist occurring during the process of what was apparently a normal labor in a slight poorly nourshed woman and the second probably caused by using rather large doses of pitultin in a case having a generally contracted pelvia. Following the rupture both cases were operated upon one dying seven hours after operation and the other on the fourth day from pentonitis

In the discussion of this paper a number of cases which have not been recorded in the literature on this subject were reported C. H. Davis.

Nicholson W R Amesthesia in Labor Ther p Gas. 1916 vl. 388.

Nicholson estimates that about 15 per cent of normal women in normal labor really n ed anæsthesia, not merely to accomplish delivery successfully but to do so without evil after effects. The remaining 85 per cent could probably be delivered as satisfactorily without anæsthesia as with it With this in mind it behooves the obstetricant to select an anæsthetic for use in labor which is not only efficacious but also safe for mother and child

Chloroform is an efficacious anaesthetic and easy to administer but its danger is great enough to preclude its use. Its margin of safety is narrow and its secondary results are frequently serious.

Ether is the safest of anesthetic agents lits use as an analgeauc has been quite satisfactory. It is cheap and easily administered

The experience of those in this country having had a considerable experience with the scopolanune morphine narcophin pantopon method varies from practically complete success to marked failure. At best it should only be used as an adjuvant to the first stage. Is a means of procuring a painless delivery it is non-efficient and dangerous the danger being due to the impossibility of individualizing the patients together with the uncertainty of the a tion of the drugs and also their relatively slow elimination.

Nitrous o'ude and o'vegen after one has had some experien in the use of the apparatus will be found too per cent efficient instead of failing in from to to 40 per cent of cases as does scopolamine. In the hands of acapable annesthetist intruous oxide and oxygen is no more dangerous than ether. Its administration especially to the deeper surgical degree should not be attempted by one unskilled in its use. With this anesthetic there is no increased tendincy to asphyxian neonatorum nor is labor prolonged nor is post partum bleeding increased over the normal.

Ferreyra F Obstetrical Analgesia by Epidural Injections of Novocaine (La analgesia betetrica po jec nes epidurales de novocann) Cron ned o o ili 37

Ferreyra reports the details of five cases in which he made injections of no occuine solution combined with sodium bicarbonate and sodium chloride according to the method of Lonen as an obstetrical analgene. The injections were made in the ligamentous membrane of the sacral region, and gave drayorable results.

Iraeta, D Annigenics in Parturition (Los analgesκου en el parto) Tesus Buenos Aires ο δ

Morphine as well as other analgesics derivatives of opium given during labor may produce slight symptoms of intoxication but may cause the death of the fectus. As to the sensational discovery of Paulin of Paris that in obstetries morphine can be separated from its toric substances, without in fluencing its analgesic properties the author accepts it with the suspicion of the existence of an oxytocic in the product injected basing the suspicion upon the presence before the period of analgesis of a short period of hyperasthesis and a concomitant increase in the intensity of the uterine contractions

The author in collaboration with Houssay and Beruti had succeeded in detoncating morphine by the use of ferments. This product newly obtained was injected in different animals and it was demon strated that the new product was of greater toxicity than morphine itself. Injecting in a sense of parturent women a solution of ferments it was found that it had an oxytocc action more ephemeral than that of the hypophysis.

Clinical experimentation showed that major doses of o az eg of morphine caused an increase in the intensity of the contractions immediately after the injection and that the pain decreased much aconer.

The uthor has devised an apparatus, inexpensive and easily manipulated, to register uterine contractions and to combine direct observation with exter

nal hysterography
Internal hysterography must be abondoned in

his opinion for the following reasons

t The balloon is difficult to place if there exists no relative dilatation of the cervix, and more difficult to place when the head has passed the perior strait.

2 During the expulsion period, the balloon is pushed out with the progress of the fortus.

3 The entire apparatus introduced into the uter ine cavity is an excitor of the contractility of the organ and modifies its rhythm and intensity

4. If the bag of waters is intact the balloon pushed in may break it and give rise to dystocia 5. It is difficult to avoid displacing the balloon

when it is in the terms.

6 It is dangerous to the mother as well as to the foctus to introduce n pparatus into the uterus.

The difficulties encountered ha e resulted in the abandoning of this method.

The apparatus consists of the brassart of Pachon, moderat and a Marcy's drum.

The brassart inflated and held by means fleather straps, is applied to the abdominal wall in the region of the fundus of the uterus at a point where it is not influenced much by the respiratory movements.

The rubber tube that starts from the brassart is placed in communication with small Barnes beg, placed in an ordinary milk bottle, whose other tube opening is unlited by another rubber tube to Marcy's drum. The author also uses an apparatus constaining of a drum, one face of which, illerable and provided with a spring, is put in contact with the abdominal wall by means of a spring the other rigid, bolds a tube which communicates with a Marcy's drum.

The registering cylinder used is no of the Balt are type, of a voluntary regular movement. As the registrations indicate the time of the beginning and termination, one can easily calculate in any segment of the graphic, the duration, the intensity and

th frequency of the contractions.

The objections which could be raised against this procedure may be due to the operator and these lection of the case. In the author's experience the pparatus gave only indications relative and com-

parable, in the same subject and at the same session.

The high and low altitude of the register depends upon the degree of compression of the apparatus on the bdominal wall and it is very difficult to find it.

the same in different subjects.

The height of the tracing which corresponds to the intensity of contraction, is not represented on the graphic, because the air pressure in the drams increases with the progress of contraction, and, therefore during the last half of the contraction the resistance opposed would be much greater than at the beginning, consequently the height of the tracing will be lower than for the first half A question which arises is. An the traces on the registering originate or graphic, the digns of stretche co tractions only or rether the traces of contractions of the abdominal muscles also? The author states that the contraction of the abdominal muscles during the period of dilatation is factor that disturbs the repairer very little because the corresponding muscles remain passive during the period of labor.

In an illustrative case a woman was chloroformed, and the apparatus applied the registrations of the contractions were equal before and during the anas-

thesia

The autho experiments upo women and ani mais led him to the following conclusions I Morphine maintains t t vicity when mixed

with hypophyseal sol tions Internal hysterography must be discarded

fo it is dangerous to both mother and feetus.

3 I the st dy futerine dynamics use should be made of external hysterography which is harmless.

4. A dose of morphine coop gr per gram of

animal weight as f t to guinea pigs.

5 M rphine is not det arcated by hypophyseal

sol tions.

6 The leaven of grain or beer not only falls t detoract morphine but seems t increase its toxic effects in animals.

The physiologic ction of antalgesin and partoanalgia according to the reenal pressure and the

paigia according t the rieral pessu terms, is equal to that I morphine.

8 Th comb nation of large doses of morphine to small doses of hypophysis annihilates the oxytocic action of the last named.

9. Solutions f leaven have less oxytocic action

than those of the hypophysis.

10. The generalized orangen that pain and pres

nancy are f ctors opposed to morphine intoxica tion is of no value

Morphine injected in a pregnant woman may

be transferred to the feetal circulation without changes.

The sensibility to the toxic action of morphine

as greater in hildre

ries greatly in different individuals.

4 In some parturients the initial dose of more phone does not relieve the pain instantly but it soon relieves the succeeding ones.

15. In 40 per cent f cases there is no indication for the administratio of large doses f morphine for the relief of labor pains.

 Products having morphine for a base, intended to prod ce analgesis in particition are of incostant ction.

7 The injection of these products during the period of expulsion has little effect their adminis-

ination in obstetrical cases is tonly unnecessary but injurious.

18. Optum derivatives do ot relieve labor pains without changing the uterine dynamic, diminishing the number and intensity of the contractions.

- 19 Parturent women subjected to such analgesics suffer more or less from symptoms of morphine in toxication
- 20 Compounds with morphine as a base may in toxicate a parturient woman without decreasing labor pains.
- 21 Generally speaking the penods of dilatation and expulsion are prolonged in analgesized partu-
- 22 The duration of labor is approximately nine teen hours for multiparæ and twenty tour hours for primiparæ
- 23 Artificial rupture of the membranes must very frequently be performed in analgesiz. I women
- 4 Analgesics increase the necessity for obstetrical intervention.
- 25 Opium denvatives used as analgesics in par tuntion intoxicate the fectus in about 38 5 per ent of cases
- 26 The administration of morphine compounds to a partunent woman may cause the death of the foctus.
- 27 Chloroform by the drop method may be used as a harmless analgesic and should be used in preference to all other anodynes
- 28 The administration of chlorof rm in urgical doses produces serious disorders in the uterin dynamics RAGLL L VIORIN
- Olivella, R. and Artenga, I F Parto-Analgesia (La partonalgia) Re- sield d S lla 0 (1 1 99.

In 7 reported cases the author has used the preparation recommended and used by Cantón of Buenos Aires as a parto-analgesic. This preparation is composed of

Chlorhydrate of morphine 4 centigrams Hypophysis extract (fresh gland) 10 centigrams Sterile vehicle 1 Tubic centimeter

The author found that in all cases pain was diminished notably and in fact was not appreciable except at the passage of the head that the contrations persuat that the parto-analgesic produces marked somoleace that the digestive circulatory respiratory and urmary apparatus were not affected that post partum vomiting occurred in only one case that involution was normal that the child in only one case was born apparer and in this ase recourse was had to artificial respiration that the infants during the first twenty four hours were stupefied and dull and required watching

II I BREAKIN

PUERPERIUM AND ITS COMPLICATIONS

D Lee J B: Puerperal Infection Che & M Recorder 0 0 m 1 4

The statutics of 1914 show that 3 500 women died in the United States from purperal infection that is 10 women per day died in the United States from purperal infection during that year. This is the reported number from the 60 per cent of the reg istered population of the United States which means that the deaths are reported and are received at the Census Bureau at Washington. In addition to those dying from puerperal infection there are a large number of women who die under an entirely different diagnosis

It is generally considered that puerperal infection is due to an infection of the parturi nt cand by germs and probably that is true. It is believed that the streptococcus causes most of these infections. Probably that is true too but other germs likewise cause puerperal infection is under the strength of the strengt

One factor that has a great deal to do with the in idence of infection is the epidemic influence. At certain sea on of the year the bacteria that are rainarily present in the room and in the dust and are acquire the highest degree of virial nee.

The conduct of labor has as much to do with the prevention of infection as the asepsis of labor. To fut it in a nut hell, the asepsis of the labor, the strik it in of gloves and hands and all implements the hadres, the mouthpiece that go with the programming the product of labor are not all there is to be lon in the prevention of puerperal infection. To this must be added the proper conduct of labor.

Cl sifying all ases of puerperal infection at the start I ecause that is the time when local treatment if it does any good at all should be instituted we can make the sveeping declaration that the local treatm nt of puerperal infection has seen its day There is still a rather marked difference on one point regarding local treatment. There are those who believe that if the physician is convinced there is d composing material particularly placental in the ut rus it should be removed at once. If a woman has an undoubted purperal infection and has a piece of pla enta in the uterus, the greatest danger he runs is the danger of hemorrh ge and it has been the author's practice wherever hæmorrhage did not exist to leave the piece of placenta in the uterus until the protective barrier which Nature throws up against the advan ement of the infection has been thoroughly established and enables the uterus to be invaded without the danger of spread ing the infection. However if ham rrhage inter feres with this expectant treatment something has to be done and there is the choice of two rem edies one tamponing the uterus and stopping hæmorrhage that way hoping when the tampon is removed that the piece of placenta will come with it and the other is immediate manual digital

rartly instrumental removal of the piece of placenta. That such a course of treatment is successful and is not dangerous has been protentine and again and has been protent by the respectable minority of men who believe in that form of treatment. The protectit e wall of granulation should not be in the bed

If a piece of placenta in the uterus is infected and is causing puerperal infection, by the time the woman has had the first chill the bacteria are far beyond the uterine wall. They have gone into the blood into the connective tissue, if they are coing at all.

If a woman has a hemolytic streptococcus in the uterus, whatever is done to the uterus helps very little because the infection has gone beyond the reach of anything that can be done locally. If she has not a streptococcus hamolyticus infection, it makes little difference what is done, because the infection is superficial and in the course of time will be cast off by itself but one should avoid doing any thing which would convert a non-virulent invasive organism into a virulent and invasive one. The operation is asked Would not a piece of placenta decomposing in the aterus in itself conduce to the development of invasive qualities of a hitherto on invasive and harmless organism. This question? has been answered Yes and N It has been said that the streptococcus living as a parasit is harmless in the genital tract, but given enough placental tissue and blood to feed on, it will develop invasive qualities, and by removing the pabulum the strentococcus will not develop these qualities. This has not been proven by experience been shown time and again that if a wound that is granulating nicely in which Nature is throwing off infection in successful way is opened and the granulations broken down, a veritable inoculation of the woman with bacteria is produced.

The other methods of treatment vaginal douches, while not very harmful, are not entirely harmfus; they do no good and had better not be given. Brushing the uterus with incurre of iodine the author discontinued long ago but one form of local treatment be till insists on and that is the removal of perincal and cervical stitiches. He believes in providing free drainage. If there is plenty of room for the secretions to get out, then there is a greater chance of overcoming the infection. Outside of the removal of the stitches the uthor uses no local treatment.

In the general treatment be still uses antistreprocesses serion. If a patient come of an with chill, high temperature prostration, and presents the symptoms of streptocorcie infection be gives see cam, of the serion. If she does not make a marked improvement, be discontinues the treatment. The author has not seen any complications

add from pairs in the foliate and urticarial eruptions. DeLee uses very few sections because he has seen no benefit from them. Neither has he seen much, if any beneficial effect from collargol and electrargol. Normal sait solution is a good divrant but he has not had the wonderful results from it that his collessmen recoller.

The author's advice is Do not be in a hurry to open a pelvic abscess. Of course, that does not mean you will alt by and let it break into the bowel or the general peritoneal cavity or break out in the skin. Do not be in a hurry to take out a nus tube

after puerperal infection. He has never taken out the uterus for puerperal infection, and he notes that there is great conservatism manifested in the opceration of removal of the uterus.

In the prevention of puerperal infection he lays particular stress on the method of cooducting labors in the hospital also the chances of infection being spread after sterile supplies are exposed to the air power in the constitution of the consti

DOWNED IN COMMITTY

Hedblom, C. A. A Case of Phlebitis Migrans. J Am M Au o 6 kml. 777

A married woman of 26 was in her fourth pregnancy in five years. The first two babies had died of marasmus the third was living and well.

The labo progressed without incident and a 7 as yound baby was born at the end of the twelfth bour by normal mechanism. No lacration of the perincum occurred. The placenta came away after ten contractions. The uterus was atonic and in applie fergot and massage there was rather more than the average amount of bleeding, but the pulse did not so above so.

The temperature remained between 90 and too.7 for the first ten days of an otherwise uncerentful convalencence. On the leventh day the patient had a dereching night wear and there was a sarpy rise of t mperature to ou paties to. The breasts were normal the fundus well down and not tender. The white count was 17 000 hemogloblin 60 per cent. There was marked tenderness and some induration over the counts of the right appleanous vein, and the legs soon became swellers and crematous. Treatment consisted in elevation, use of the fee bath absolut rest etc. After three days there was

marked drop in temperature and pulse, and, although the tenderness and swelling extended progressively down to the foot, there was a gradual but steady improvement until the beginning of the fourth week. At this time the temperature again rose sharply to 04.5° pulse 135 and marked tenderness, indurati n, and swelling developed in the right thigh. The patient was nauscated a great deal during the next two weeks, vomited at inter vals, and complained of pain in the epigastrium much aggravated by food The pulse remained t about 30, became weak and irregular and there was increasing prostration in spite of the fact that the swelling and tenderness in the lers all but disanpeared

During the sixth week of illness these symptoms recurred first in the left and then in the right leg with pain in both legs and feet which became to severe as I prevent legs except after mophine. There foll wed, however a period of general improvement during which the patient was sign ble to take food, and for several days the pulse and temperature remained at about normal. During the cighth week industation, tenderness, and swelling appeared progressively over the left side of the neck stills, arm, and left chert. There was also increased swelling in the left dank and lower abdom-

and wall which was spastic and very ten let to pal pation. The swelling in both legs increased and pain in the legs and feet became so severe as again to require the administration of morphine. The temperature was from 100 to 103, the pulle from 130 to 140 and at times almost impulpable. Durmig this recrudescence which lasted about two weeks gangrene developed over the antenor aspect. I both feet which resulted finally in the separation. I the whole thickness of the skin and partial sloughing of the tendon-sheaths.

After another interval of improvement ther was a fourth relapse during which the right side if the neck, the right axilla and arm became involved and then successively the occiput whole scalp and ta e During the height of this attack sharp pain de el oped in the chest aggravated by deep respiration but no friction rub or other signs were chinted There were nausea and vomiting lasting 5 v ral days. The voice became husky and the patient complained of severe headache and pain in all af fected parts but most marked in the feet symptoms abated toward the end of the tenth week for a period of about twelve day. This vill wed by the sixth and last relapse characterized hy abrupt me of temperature from normal to 101 the pulle was accelerated from 120 to 140 and again became irregular and at times almost impalpable beginning of this attack there was a good deal of vomiting and violent headaches. The swelling in the neck and scalp which had begun to subside all a increased. After four days the patient became erv drovsy suffered lapses in memory and anally be came partially irrational for several day thalmoscopic examination papillitis of both optic nerves outline of both disks entirel list vision almost normal but with duplication of objects

The patient was discharged in the nineteenth week in good general condition. Nine months after the onset of the illness there was no swelling or disability the patient was in excellent health and of maximum weight and was able to play golf and tenns. She was admitted two months after this time and an appendectom, one for subacute appendictible.

Commiskey L. J J Routine Wassermann Reaction in Hospital Obstetrics 4m J Ob t \ \ \ \ \ \ \ \ 0 \ 6 \ l\text{cmi} \ 6 \ 6

This report is based on the routine Wassermann tests in 1821 mothers and 10.4 newborn infants the larger number of mothers being due to the fact that the women were subjected to the test eleven months earlier than the infants as a routine and also that some mothers left the institution undil ered Of the mothers tested 145 or 8 per cent w re

positi e 26 of 14 per cent ere doubtful and 11 negati es or 06 per ent had infants whose reactions were positive or doubtful. Only 6 or 18 per cent of these women with positive reports gave any history or shived any signs of viphilis leaving 110 r by per cent with politive reports who showed nother chin al evidence nor gave a hastory of the die. From this it can be seen that many cases would have escaped diard just but for the routine Wale remain reaction. The in lusions are as foll.

The routine Wall ermann reartion is the ideal method to the detection of robbits in the pregnant or man or all near the ideal as our present knowledge will permit

From this comparati elv small number of use it uld seem that syphilis has but a slight infu n e on the length of gestation but does seem to produ a much higher per entage of stillborn infant

That the use of the blood r serum from the uminical cord for the treatment of others is unwise and I ngerou, without the Wassermann being done upon both the tottal and maternal bloods

2. That the death rate among hildren of Was sermann positive mo hers is four times greater during the fir t ten day of life than in the case of children where both mother and hild are negative C H Dyurs.

Iyer H \sim A Case of Stamese Twins I.d.

The author reports a ase of a woman aged 26 VI pura who had been in labor for three da 3. Upon his arrival he found a fortal head and left forearm deli ered. These had been exposed for six hours on vaginal examination a second head, with its face turned toward that of the delivered one was found. Attempts to push this head into the uterus failed. With some difficulty forceps were applied to the undelivered head with gratifying results. A common placentar was delivered shortly.

The twins were found to be attached by the rib cartilage. They were lying on their sides facing each other and the left hand of one was between the heads. The heads were distinct and all tacial or gans well formed There were four hands four legs two separate vertebral columns and a common abdomen covered only by peritoneum. Ther were two separate pelvic bones and male organs. A single cori passed under the pentoneal c ering of the abdomen The small and large intestines were found occupying both portion of the abdomi There was a single h r an i spleen nal cavity There were two pairs of kiln ys a ingle heart two lungs and a common haphragm. A case of Stamese twins - both tillbirths

GENITO-URINARY SURGERY

ADRENAL KIDNEY AND URETER

D Villa, S. A Case of Malignant Tumor of the Right Kidney in a Child of Four Years (Sopra un case di tumore maligno del runs destre in un hambino di 4 anni) Res di di fedesi 9 6 xiv

Malignant tumors of the kidney whill of frequent are fairly familiar in pediatric literature. During the past years in the pediatric clim of th University of Rome, 14 such cases have been observed.

The first impression given by the case reported by DeVilla in a girl of 4 years was that of an echinococcu cyst of the liver. The differential signs, how ever ruled this out as well as other possible temors, and the ultimate diagnosis of tumo of the right kidney was arrived at and intervention decided.

Under chlordorm an incidion was made in the creal region and the creal pentoneum opened up. On clearing way the periorcul tissues and adhe-loos the tumor was found. The adhesions were between the antersor face of the tum—the abdominal walls, and the colon. Luxating the tum—through the wound it was found to be attached to the right kidney by a pedicle. With its appendages the tumor weighted early 800 grams.

Histological examination showed that the tumor consisted wholly of sarcomatons, partly myroma tous color tussue, except at its interior pole, where there was a zoo of longral renal substance. In the lower pole was also found urinary cyst and some small here ribagic cysts. The tumor was composed mainly of fibrous fascia and young fibroblasts. Thus is the usual finding in histologic examination of malignant tumors of the kidney in

The subsequent operative history of the hild shows that except for a bronchopneumona there were no complications and five months later there was no evidence of recurrence.

The author gives a summary of the previous cases which are recorded in the clinic. The general mortality if non-operated cases is so per cent. In the operated cases to operative deaths averaged 40 per cent. deaths by recurrence after operation, 45 per cent. definite recoveries, 7 per cent.

W A. BRENKAN

France A. Th Origin of Hypernephroma of the

Of 34 so-called hypernephromata studied by the authoron was almost undoubtedly a neoplasm riginat ing in an accessory nest of cortical adrenal cells, and the patient who was a woman, aged 38 was 6 feet in height of excellently developed musculature, the hair on the head, the chest arms, and legs was thick, coarse and abundant and there was a distinct moust che. The mammer were undeveloped and the chest was 4 the male type.

In a of Fraser cases of so-called hypernephromata the morphological evidence indicated that the tumors were deri ed fron the tubules if renal adenomata and had no histogenetic connection with the drenal cort z. For this reason he suggests that the term hypernephroma be used only to include t more which are undoubtedly of cortical adrenal origin, and that the term neophramata be applied t that large group of renal tumors to which the design natio of hypernephroma is now given. In support of thus ontenti he points out that the primary struct re of adrenal turn rs is essentially different from that of t more of renal origin, that the primary of drenal tumors never imitates that of renal tumors, but that the primary tructure of certain renal denom t can tan early stage through p old ration imitate the primary structure or to mors frenal rigi Both tumors of renal and of adrenal origin are capable of undergoing secondary degenerative and malignant changes rendering their histological features almost dentical.

Kried, A. Abacese of th Kainey Cortex and Its Helation t Paramephritic Suppuration (Ueber den abaces der Nierenrinde und seine Beziehung auf paramephitischen Eiterung) Beitr z. Eli Chir. g δ xxi. 4 km².

The patient in the case reported by Krieg was a girl of 5 Th history howel influence and freq ent neck inflammation. The present discussion began suddenly with pains in the right lower abdominal segment high fever tendency to womit, etc. Appendixti was if sposed and lapratomy do e. The appendix was found the normal. On the und pole of the right idder a cherry-sized tough growth was fell. On freeling the kidney this was found to be a cortical abscess. About 10 abacesses from the size of a pin t that of a pea were found scattered on the surface of the kidney. The kidney was extirpated and recovery has per sixted for the two years since the operation.

The a thor thinks that the observations are of importance with regard to unliateral kidney abscasses, in that the case throw light in the method of development of such abscasses. Itself of framatogenous origin, the corrucal abscass had directly attacked the fibrons capsule and involved the neighboring tissue. By this means the way was opened to the fatty capsule and it is seen that the developed

paranephritic abscess condition had its origin in TI A BRETL the cortical abscess

ber perton

The author offers the foll using n te rthy on clusions

1 A mechanical problem is but of ed under good mechan cal principles

2 uc ess is 1 pendent upon the derreet which normal anatomi al and phy i I meal conditi ns are approached

3 The kidney man be wounded fixed or constricted with impunity

1 Decapoulat n e her partial o complete does net impair kidnes tun tion.

The most at nal method of secur g the kidnes in position after it has become a wand rer to such a degree as to demand operation is that of emoving the cause and aiding in the reconstruction of a natural support.

6 Any permanent artificial support is dangerous if not completely destructive to the kidney's functional activity

7 The rolled-up and transfired capsular flap offers a perfectly adequ te hold for one end of the anchorage and the muscular and fascial layers of the loin the same for the other end, without sutures which emerge through the skin.

8 If the anatomical relations of the Lidney can not be permanently readjusted without destruction of its functional activity it should be either let alone or removed.

Pedersen V C. A Seven-Glass Urinary Test Y Y M J 9 6, clii, 867

The necessity of a cimical means of recognizing protated disease apart from seminal vesicular disease and of vesicular disease and of vesicular disease and of vesicular disease of one side apart from that of the opposite side, and likewase of the prostate ind ced Pedersen to evolve the procedure described. He does not claim that it is also it ely accurate but says that it will furnish the chairal basis of operation very satisfactorily by demonstrating whether the pus is chiefly or solely in the prostate as distinguished from the vesicles or vice verta, or in one vesicle independently of its fellow or of the prostate gland.

The author dwells upon the anatomy of the organ in question, and shows with the aid off illustrations how this test can be logically carried out. He per forms this test to two two though the creating and the two-stage. The patients bladder should be reasonably full further or should be filled at the tim with pormal sail solution. For each specimen 100 to 150 ccm. of unite are necessary.

In the one-stage method Glass 1 is obtained by irrigating the anterior urethra as far back as the cut-off muscle before urination. The wash water will show the amount of involvement of this portion of the urethra.

3 Glass 3 which he calls the anterior urethral control giass, is obtained in the same manner and its contents are from the same source While obtaining Glass it is advisable to massego the urethra upon the eatherer in order to express the contents of any infected u eithal follides.

3. Giass 3 is obtained by having the patient pass about 50 ccm. I bladder unine. If the bladder is normal this glass will contain almost solely the contents of the posterior urethen, whose nature will be ab with yith indexocope as the products of posterior unrehritis in uncomplicated cases, or of this lesion combined with drainage product from the prostate and vesicles in complicated cases.

4. Glass 4 obtained by cautions catheterization with a different catheter from that used in the ir rigation of the anterior our thra, will show with a microscope that there is no pyunia, or that if present its origin is citien vessel or renal

- 5. Glass 5 is called the p outsite glass to obtain which there must be considerable unit left in the bladder or that organ must be distended with nor mis sait soi tion. The protrate is then massaged solely along the lateral borders of the lateral borders of the lateral looks where they forms a distinct unless for the finger in the rectum between the prostate metally and the facan of the pelvis outsade it. Great care must be taken to wold the middle of the prostat along the urethra where the course if the ejaculatory duct lies. After this massage the pat ent passes 150 cm. 6 bladder content and this presents prostatic secretion normal or pathological for xamina til.
- 0 Glass 6 is the first seminal vesicle glass designated in accordance with the side from which it was taken. The author prefer to elect the vesicle which seems to be the least duesard on the ground that its contents may be far more ormal, and he always begins with the ormal vesicl if its fellow seems solitary in i volw ment. After massage of this organ, the patient must evacuate another 15 ccm., which will co tain so purely the products of the massaged vesicle as 1 mak the specimen of great clinical val.
- 7 Glass 7 or the accord seminal vescular glass is brained in simular manner by massage of the remaining seminal vesicle. In sterlity the sevenglass test carried out in the usual manner will also whether or or both testicles are involved and whether or not there is atrophy of the two seminal vesicles.
- The two-stage method consists in earrying the examination through Glass 6 in the ordinary way just described, and then postponling Glass 7 until a subsequent visit. The seake which at the first slitting was not massaged is now exacuted and the patient empties his bladder into one or two glasses, according t the cull f ra control specimen. This suspected, and the contents of one visible must be carefully separated from those on visible must be carefully separated from those of its fellow.

The author illustrates the value of the seven-glass test with a chart of specimens obtained from numerous cases, and he also gives several case

reports.

In conclusion, Pedersen says that this test is not infallible and no such claim is made, but no test possesses the quality of infallibility. It is not self sufficient and the uthor does not so state but few tests are really self-sufficient not even the \text{Nry which commonly requires corroboration or is itself only corroborative. The seven glass test requires, first of all, digital skill in massage as such, and then with the parts of the prostart and seminal calcier which are to be reached and with those part of the same organs which are to be vided during the massage which this test delimits. It will be well for the beginner to study many patients per severingly before being satisfied with his own skill the mainplusition, and therefore convinced of his

own deductions from the test

Cameron D F: Variations in Renal Function Dependent on Surgical Procedures J In M Ass. 19 6 levil 705

Cameron's work shows that in surgical diseases of the urinary tract the phenolsulphonophthal in test and the blood urea test are practically parallel although there is one type of case in which the phenolaulphonephthalein exerction is dimini hed but the blood urea is normal. He also sho relief of any type of urinary obstru ti it in reisc markedly the percentage of phenol ulr honephthal in excretion accompanied by a drop in the llood ur a The most interesting porti n of the article the result of the d termination of blood ur i ift r operation with nitrous on less tygen and the in with rebreathing. These patient all how I an icrease of the blood urea som of them just high After operations under ether anasth sia the more we in the blood urea if any was much less in n e this small series of cases would fail the upport the contention that nitrous-oude-overen ther in sesthesia has a less del terious effect on r n l eth ciency than has a pure ether anasthesia

The author summarizes his results as f !!

The agreement between ph nol ulthon phthal in and blood urea tests is as a rule very triking though not infrequently a low ph nobulthon phthalenn excretion is associated with in rm loronly moderately increased blood urea one in time.

These tests are of great importan e in selecting the most opportune time for operation so f r as

renal function is con erned

Following an operation under a gen ral annathetic there is, as a rule an increase in 1 lood urea concentration. This increase is most marked after operations on the urinary tract and e-pocually on patients who already have diminished ren if function. In a small series of cases the increase was lightly more marked following operations under gas ovegen-ether anasthesia than following similar operations under ether

Blood urea determinations are of great value in the diagnosis and prognosis of urene tate. Not interquently blood urea on entrate near the determined when other renal function test are very

difficult or impossible to use

In this investigation definit symptoms of uramia in uncomplicated cases appeared when the blood

urea concentration reached 180 to 200

There is a definite group of patient who have a low phenolsulponephthalein exerction but a normal or approximately normal blood urea concentration. Many members of this group withstan I a general anasthetic without any compile ations due to r nal mulficiency. A D LIAPTY SET

Pedersen V. C. i The Diagnosis of Ureteral Calculus V. 1. M. J. 19.6 cii. 069

This method is not intended as a modification for or as authoritive of that described by Burton Harris but rather as an application of it to the Brown Buerger cystoscope The method of preparing the

way tip itself and the compound if way a the same as those detailed by Harris, likewise the tachnique of passing the wax tipped filiform into and coiling it within the bladder full of urine or of boric acid water artificially introduced. The sheath of the Brown Buerger instrum at has a very will fines trum which when passed along the hliferm gul le in the ur tha chafes and even causes smart hemorrhage fr in the deputetha in many cases. In order to ay if the the author has devised an obturator have ing a will I tat the vesical end and at the handle of th shith through which the uliform guid i thraird. The obturator protects the mu osa and permit on y intreduction of the intrument with ut pain or blacking. The dit n ling fluid in the bla lder escapes through the slots of the obturator Thin the atheterizing telescope is passed the dist nti n ren wid and the wax tip brought into view exactly as Harris describes rotated complet by under the eve for demonstration of any scratches and then passed into the ureter. The author leaves the file torm again t the tone aft r rubbing it upon it and thin ith fram the cystoscope and the filiform as on in trument. The di tance from the eye piece to the way tip is alm >t the Nact distance of the ston 1 om th' mouth of the ureter Thus method will be tound direct imple and accurate and in adarting the Harris method to the Brown Buerger instrument the use of a Nitze instrument is unnecessary for which instrum at Harris originally des ribed his technique

BLADDER, URETHRA, AND PENIS

Legueu F Extraction of Bullets from the Bladder by the Natural Route (Le tract par les oles aturelles des balles de l'esa). J d'rot 9 6 l, 5 5

Fragments of shell or shrapnel balls on account of their irregular form and sometimes their large call ber must always be removed from the bladder by the operative method

Rule bullets on the contrary being smooth and of a suffi iently small caliber can be removed through the uretha Legueu has thus removed all such bullets which he has found and con iders it the method of choice

To carry out this procedure it is necessary that the bullet be quite within the bladder free movable and have no concretions. Radiography in two different positions will gen rally determine some of these conditions but cystoscopy mut to be relied on it alone shows without error the presence the situation and the moditiity of the bullet and it alone, an show all the conditions which it is necessary to know before proceeding to extraction.

Legueus procedure is v. r. umple. Il uses. No so lithorite which he ha adapted for this pur pose, and by touch alone performs the viraction. The instrument is introduced into the I ladder by the ureth in the usual way just as f a stone were to be removed only that the builter mut the seized.

either by the point or by the base, and not transversely. The dimensions of th urethra easily per mit extraction. No ansesthetic is necessary unless the bladder is extremely sensitive or the patient cannot stand the proceeding. W.A. BENDOMS

Turner G G Foreign Bodies in the Bladder Resulting from Gunshot Wounds Lessel Lond 9 6 exc, 958.

The autho cites three cases of wounded soldiers in the present European War i which the foreign body had presumably lodged in the bladder at the time of the causality for in each instance there was some urinary trouble from the outset. The lodgement of a missile in the bladder is an event well recognized in all campaigns. In most museums there are pecimens of calculi in which the ucleus is formed by some type of bullet. In th \ray investigation of such cases plates should be made with the nationt in various positi as and with the bladder empty and distended. Marked alteration in the position of the shadow will then be a guid as to the freedom of the foreign body in the viscus. A routine cystoscopic examinatio ought also t be carried out, for there may be some non-metallic f eign body in addition to that shown by th \-rays. or the foreign body may be entirely non-metallic, and a negative \ ray examination is therefore not enough to establish the diagnosis.

It is Interesting a observe how the would in
the hisder spontaneously closes. Small foreign
tooline the yet end I escape with the unce but
those that cannot negotiate the urethman way some
times be asfely removed in the eye I an evacuating
eather. Expure, using a specially modified I in
trite, has removed riff and machine-gun bullers
per urethram rapidly and without general anna
thesia. For shrapine bulleta, large or ragged
fragments of abell, or incrusted foreign looders
the uthor considers the suprapuble rout the
method of choice, and he believes it will certainly
be the safest in the hands of those without special
training. H. A. Moonx

Saviozzi, V Treatment of Gunshot Wounds of the Bladder (Contribut alla terapia della fent d'arma da fuoco della vesica) Clin chir 9 0 xxiv 324

Savioral reports two cases of gumh t injuries of the bladder treated by suprap the cystostomy and tampoof g the bladder opening with f vorable result. In one of the cases there was found located I the bladder a bullet as well as some spiculae from th fractured innominat bone.

Gunshot wounds I the bladder are more frequent than any other lind of bladder wound. Bartels collected 85 such cases but it is only very rarely that as in one of these cases, abo y fragment is carried into the bladder by the projectile. Bladder liquies of this kind are classed either as intraextraperitoscal. In the intraperitoneal variety the prognosis according to most writers is absolutely fatal Although this p ognostic conception seems rather enggerated to the utbor yet in the statistics of 5 cases, collected by Rivington, of intraperi toneal cases there was n recovery nor was there a recovery in any of the cases reported by Bartels.

Extraperitoneal injuries ha e however, a more favorable prognosis, but it is difficult to determine whether the injury is intra or extraperitoneal as the early ymptoms n both are identical.

Regarding treatment the prime eccessity is to arrest hem rrhage and assure the flow of urbox Some recommend the seake à dement extraperal toneal injuries, others recommend suture of the bladder and laparot my in either ariety of in jury

As to the treatment adopted by the author Lecytostomy with tamponad i the bladder (with laparotomy also i the tars case) he thinks that the brilliant result obtained authorize him to strongly recommend this procedure because it is rapid, asle and in serious asses can even be carried out under local anesthesia. In these cases aut re of the bladder was technically monable and in gunshot counds accompanied by a perivencular harmorrhage and the difficulties of suturing are such as to favor the simpler and equally safe method dopted by him.

Davis, E. G. Vesical Drainag (Historical Review and Presentation of New Apparatus. J. Am. M. A. 9 0 1 vl., 680

The thor review the various forms of apporatus used fo urinary drainage following suprapublic cystostomy. The ideal apparatus permits un nary leakag from the time of operation mid the hatul is halder requires littly attention causes no no ven ce to the patient and is simple and inscreening.

The utbor describes and illustrates the appeara tus w used in the James Buchanan Brady Urological Instit t Two bottles of 8- pd capacity est on stool o on the floor beside the bed I th larger one is a vacu m, which is grad ually decreased strength by leakage of air through a mu te capillary glass tube from the small er bottl W thun the smaller bottle th air pressure is slightly less than one atmosphere so that by virtue of this difference the rine is draw out of the bladder through a catheter nd tube into the smaller bottle. As the urin drops int this bottle, it replaces the air which has leaked into the vacuum of the larger bottle. The capillary tube is placed within the vacuum bottle to keep the apparatus as compact as possible

The air pressure within the doe bottle is regulated by small U-shaped manometer of giast tubing with a lumen of 5 ccm. For the sake of co-ventient and safety the manometer is also placed inside the vacuum bottle. In the bend of this tube is a small amount of mercury which if sufficient pressure is exerted, will permit air t pass in either direction. This furnates a safety valve which p events the

pressure within the urine bottle from lift ring from the atmospheric pressure by more than 20 mm of mercury and also prevents the catheter from Cortiing more than the gentlest suction within the blad ler

The care of the apparatus is very simple unne bottle must be emptied when full and the air in the larger bottle exhausted at least tyforty-eight hours WEL *

Erkes F Manual Expression of the Bladder in a Spinal Injury (Zur manuil n E.p.e. 1 Blase bei Rueckenmark in tunin M. s. med Weks in 1010 l. 5

In the case reported by Erkes there—a a pene trating injury by a gun h t which trace is spinal column. The entraine was at the strain lary line and the outlet a fittle to the richart of the spinal apophysis of the tinith label entrained. There was complete loss of chasting in all motion in both lower limbs a well as biller and retil paralysis. To avoid catheterization the author practiced manual expression (the lift is through the abdominal wall which by this method is more pletch evacuated.

Lamnectomy was done with extra u n or me osseous fragments which compressed the lura mat r Later in the day the pati nt sull alv 1 | pet grave abdominal symptom and fill with imposms of bladder rupture. At autopsy, an uli rous perforation of the fundus of the bladlir war unit.

The author thinks that manual expr > 1 n or the bladder should only be man when the reil no eldence of cystitis or any alteration of the vestal walls but that when the man be a used the method is capable of giving good ervien selvice cases.

Rochet Total Ischlopuble Disconnection of Deep Perincul Fascia in Order to Reach the Deep Leethra and Exteriorize the Prostatoresical Region Deansert on Islamp beam total of laps we permale me po me blue lu tre prot und text in the la regio prost toal 1 L k y o cui

Rochet reters to the arying procedures with the urgoons he re-crited to in order to find a relatively easy mode of cc> by the perineal route to the deep male genito-urin it organs. Young sperineal operation Boeckel anorectal oper to in difficulty of Folkes occupenical rout as well others a review.

The author however finds all these methods limited and in seeking a method for reaching the deep perincal organs and bringing them completely out of the creavation has realized it by a massive mobilisation of the whole deep perincum by lateral disconnection of the deep perincum by lateral disconnection of the deep perincul face, and its complete peripheric detachment from all the esseous techniques of the description of the deep learner of the description of the deep learner of the description of the d

The operation is done in four stages. In the first the penis and scrotum being tightly drawn up a reversed V-periocal incision is made. The summit of the V corresponds to the subpublian angle and the sides of the V follow the schilopolis branches.

This is practically Young a inclaion.

The second stage condsts in the stripping of the deput threat from the rection as in an ordinary prostatectomy penetration into the recto-urethral triangle, section of the recto-urethral muscle, and separation of the anterior face of the rectum from the posterior face of the prostate.

I the third stage the membraneous urethrs is cut through immediately behind the bulb immediately before the deep perincal fascla. The anterior end of the urethra is alightly loosened up including the bulb and drawn away so as not to mask th field of

operation.

The fourth part of the operation consists in an attack on the lateral attachments of the deep perincal fascin and on the deep perincum as far as the internal edge of ischium. This part of the procedure gives complete access and freedom of action on the prostate and lower portion of the bladder

The author has carried out this operation in two cases of cancer of the prostate and be thinks the operation is indicated in cases requiding extingation of the cascerous protate, also when th! were part of the bladder is attacked by localized explains. The high route of approach is work cases is difficult and the field is far from the reach of the finger and instruments. W. A. Barraum.

Thomas, B. A., Siter, E. H., and Randall, A. Am putation of Penis for Carcinoma; Conditions Four and One-Half Yeurs After Operation. 4 s. Surg. Phila., 9 6, Ltdl., 735

The case is reported of a man of 55 who in October of 1 had been operated upon for a typical cardinoma of the glass penis, involving the orethra, with metastasis to the inguinal lymph-glands on both aldes and amputation of the penis close to the p bit arch.

Interesting features of the case are Absence of recurrence, although complete estirpation of the penis with perincal urethrotomy was not done, and good functional result (ability to urinat in standing posture)

Del Valle, D: A New Operation for the Treatment of Varicocele Sug (v Ob t) ii

The operations for the treatment of varioxele are numerous but none of them have fulfilled all that is required. Del valle considers the tollowing operation simple and the results better than those obtained by the presentation.

ation simple and the results better than those obtained by similar procedures.

I Make an incision 5 cm long on the ext rual abdominal ring exposing to view the ring with its

cord.

2 Dissect the anterior group of veins separating it from the other elements of the ord. It is not necessary to dissect the spermatic artery. In all vanocedes it is generally the anterior groups of veins forming part of the cord that is affected besides anatomatically the anterior group has a greater num ber of veins and is more important than the posterior group.

3 Divide the antenor group into two sul groups anterior and posterior. Place a catgut figature on the posterior subgroup one inger a breadth above the tesucle and a silk ligature on the antenor one two fingers breadth above the former on holding the thread.

4. Make an incision on the fascia of the external oblique within and parallel to the internal pullar of the ingunal canal introduce a forceps through the incision, directing it so as to come out at the orline of the external abdominal ring seize the ends of the silk thread and pull through. Thus the entire an tenor group of verias passes through the opening in the fascia and by means of a sittle hit is fixed to it after ascertaining that the testicle has remained at the required helicht.

5 When the posterior group of vins is the one affected the operation is the same except that the opening in the fascia is made outsit, the external pillar of the inguinal canal and not within the in ternal pillar.

Where Freyer's operation has been correctly executed there is often the ulterior appearance of calculi in the vesicoprostatic region owing to the existence above the prostate of an normous cavity into which the alkaline urinary salts are precipitited. The condition is not imputable to the surgeon but 1 a definite result of the prostatectomy

I sum ou thinks that prostate-tomy should be ill will up by lisinfection of the bladder as long as the union of not completely limped and that the littriulit pocket occurring successive to prostate term is should be suppressed by a perineal resection at this pock this capable of permitting the formation of secondary and even primary calculing lebral to

In twis away in which Loumeau observed see in lary calculi subsequent to transvesical prosta to withree times they were clearly attributable to post-operatory prostatic cavities chargeable to the operation alone. W.A. BERNAN

Peterkin G S Calcareous Degeneration of the Prostate Gland Ann Surg Phila. 1916 Ixili

The patient givears of ag sustained two trau ma to the uretha by falls followed by copious puru lent discharge from the uretha and symptoms of cyatitis which continued for thirteen years, when a progres iv enlargement and hardness were noted in the prostatic area. Palpation per rectum revealed a round smooth stony hard mass, the size of a m dium sized orange. Cystoscopy showed general cystitis trabecular cavity with tennerous pus prostatic uretha showed phosphatic masses skiagraph revealed a large calcareous mass in the prostatic area, which was removed through a supra public cy totomy. The mass weighed it grams Ten days following operation the patient died sud dealy from secondary harmorrhage. Autorsy was refused 1 5 KOLL

Morton H H. Suprapuble Prostatectomy Med T mes 916 xh 150.

Morton describes two hypertrophic prostatic cases one 73 years old on whom a prostatectomy was done th other 84 years old upon whom suprapubic cystotomy was done for drainage as preparatory treatment for prostatectomy

The first patient had led a catheter life for two years. This condition Morton designates as the third stage of hypertrophied prostates Kenal func tion tests had shown favorable results. Rectal exam ination demonstrated that the enlargement was high up in the pelvis and for this reason the supra pubic route was chosen Hagner's bag was used to control hamorrhage instead of gauze packing for merly used by the author. Freyer's drainage tube was now supplanted by one one fourth its size in order to guard against a post-operati e fistula. lesser intake catheter was used occupying a considerable lower level than the outflow tube. A through and through silver wire suture was used in closing the wound

The cystotomy case was done under stovain spinal anæsthesia. Outsid of a bladder hæmo

thage five years ago the putient had been free from trouble until the past few days when difficult uri-nation occurred. For f rty-eight hours retentlo was present, necessitating catheterization. Rectal examination found a middle lobe enlargement. A catheter was fixed in the bladder and contin ous drainage allowed after a few days of gradual empty ings. However, the continuous drainage became faulty the patient flighty and townic. On this ecount spinal anasthesia was selected instead of

ether Cystotomy was done and a jack-stone calculus removed. The prostate will be removed after the drainage has prepared the patient to with

stand a prostatectomy

Morton considers a low specific gravity (this case 1013) with albumin, pus, and blood as prohibitive from ether or even gas and oxygen anæsthesia. He also considers cocaine unsatisfactory Spanal angethesia with stovaine 0.08 lactic acid 0.0 bsol t alcohol o a distilled water on ad cm is his pref erence.

The utbor ca tions that the patient be alghtly inverted after the spinal injection in order to keep the stovaine which is lighter in specific gravity than spinal fluid from leaving the lumbosacral region and thus prevent death from paralysis of the resplratory centers. C. E. BARRETT

Perrier C. Transverical Prostatectomy Under Local Ansesthesia (La prostatectomie transcisicale sous anesthesis locale) J alarel q 6 v1, 509

Perrier reviews the various attempts which have been made t carry out prostatectomy under local or regional angathesia. He points out that in most of these the method has necessarily t be m re less supplemented by a general anasthetic.

The author's method is a combination of these procedures which he avers has given him full sat isf ction as typified in the five cases he reports I detail the combined method is as follows

Anaesthesia f the belominovesical wall by of no ocume adrenally solution 1 200 the quantity used varyl g ecording t th stout ness of the subject.

2 Angesthesia by infiltration with the sam so-I tion of the bi-ischiatic line. This will allow f

deep painless injections.

3 The left index-finger being introduced into th rectum, injection is made with long needles to 15 cm.) under the prost tic capsul cording as the liquid is injected the capsule is felt to rise and extend.

4. Injection with similar needles of the sacral

perves with a solution 1 100

Perrier is of the opinio that his cases show not only the harmlessness of the procedure but the posalbility of pplying it in cases which are most difficult from a technical point of view i.e. with very obese subjects where the prost t can only be ex posed with m ch difficulty Sloughing of the edges of th wound, as noted by Legueu has never been observed In co clust he thi ks that a prost tectomy or be performed inder local anesthesia with the same faculty as a hernia or golter W A. BRENNAN operation

Lydston, G F Sex-Gland Implantation J 4m 1/4 o l 540

The a thor gives an exhaust: summary of his previously published experimental work in sex gland implant tons with material taken form dead bodies and reports four ddition I cases of successful testicle mplant tions. In e ch case transplan t ti was made t th acrot m f testicle alone or f test cl and epid dymis from dead h man bodies. One patient aged has dements precox and tiftee m the fter operation sho decided im provement I anoth pat t ged 20 a double impla tation was don because of bilateral complete trophy of the testes, with rest ration of virility and impro ement in physical and mental vigor

The thor beli ves that the sex-gland h rmone is the most powerful cell stimulant utrient and regenerat kn wn t medical science d that sex gland impla t tion preserves hormone production for prolugged period. There is good reason to behere that physiologic and therapeuti dvantages may be permanent. In none fith cases thus far observed has the mpla ted than disappeared prior t twelve or eighteen mo the The impla t tion may be repeated J B CA METT

Loumeau Diabetes nd Prostatectomy (Diabet et prostatectomie) J d méd d Bordesux 9 6 l trin 35

Loumen clates the case fa prostati of over 7 wh fo the past three o four years had shown gly cosuria which at the time of the examination amou ted to 60 grams in twenty for hours.

A two-st ge p ostatect my was do e with most excellent results and was followed by restoration of sevual and physical f neti ns I this case th diabetes which was of rthritic origin had t ward result on the prostatectomy which as a matter of f ct cured the glycosuria.

Loumeau therefore thinks that contrary t the general opini diabetes except in very severe forms in t an operatory contra-indication.

W A. BRESTAN.

SURGERY OF THE EYE AND EAR

EYE

Stenvers H V The Clinical Significance of Radiographs of the Orbital Region R diel & Elect oth p 10 b x 411

The author endeavors to show the value of mak ing radiograms of the head in atypical positions He especially presents positions to show the rbital region citing four cases in which the diagnosis could not have been made either by the stere? scopic lateral or anteroposterior plat is

Before using these new positions in attempting diagnosis he carried out a number of experiments in which he placed a metal object over the various lines of the anterior fossa and also covered as me of the projections with lead foil. In this way he dom in strated that the interpretations by Rhese of er

tain markings were incorrect

Owing to the asymmetry of the injividual kuli and the wide variation in the skulls of dir rint individuals it is impossible to lay down a parti ular or definite procedure Each case calls for a slightly different position of the skull on the plate author emphasizes the value of taking radiographs

of both sides of the individual kull for omparison The usual position in obtaining plates for the proper study of the orbital region as stated by the author is as follows The plate is so adjust I to the face that one edge rests upon the zygoma of the side under examination and the other upon the ridge of the nose

The conditions demonstrated by this m thod of

examination were as follows

In the first case a lymphosarcoma of the orbit the change demonstrated by the plate was an in crease in the size of the fissura orbitalis

In the second case a new growth had caused the absorption of the crista galli and lamina "ribrosa a condition which could not be demonstrated by the usual lateral plate

In the third case there was a fracture of the floor of the anterior form, and heally a harmorrhage into the orbit. W A. EVANS.

Bourgeols, H Twelve Observations of Orbital and Peri-orbitul Fistulus (Douze observations de fistules orbitaires et perioro b taires) P f ## 916 Th 5

The author reports on twelve cases of fistulæ in the orbital region of which se eral were consecutive to war injuries. These were accompanied by lesions of the adnexal caviti is of the nasal fosse and sinuses In the presence of su h a fistula a tertiary histulized osteitis must always be thought of Foreign bodies of small dimension e en small osseous fragments

sufn e to cause these suppurations. Large opening mu t be instituted and the offending body searched ut the tinger aiding the eye

The osteitis will be curetted until the healthy os cous ti sue is rea had. It is not less important to effect osseous reparation while avoiding second ary infe tion. This is best off-cted by leaving the osseou wound alone and suturing the operative wound as early as possible allowing only sufficient II I BRENNIN opening for drainage

Rhodes, G B Pulsating Exophthalmos S Phil to Cl 390

In 1908 le Schweinitz and Holloway reviewed the r port d cases of pulsating exophthalmos prior to that time Since then the author has been able to ollect 52 cases from the literature and to these he a lds one of his own

From a tudy of this series of 3 cases it appears that a of them were of traumatic origin o occurred spontaneously while in the cau c was not given In the traumati cases there was u ually a latent period of about 21 days before the first vimptom the bruit appeared. The average age of the patients was thirty-six Exophthalmos occurred at later periods varying from a few days to a month atter the appearan e of the bruit Pulsation is a later symptom usually appearing within a few days after the exophthalmos has been noticed. Loss of the pupillary reflex with persistent dilatation of the pupil occurred in many cases due to the la eration of the carotid plexus of the sympathetic all cases showed an in rease in the ocular tension but only two developed an absolute glaucoma Diplopia, hæmorrhages or ædema of the retina tortuosity and dilatation of the retinal veins were ncountered with great frequency. Certain nerve lesions such as optic nerve atrophy paralysis of the motor mechanism of the eyeball die to lacera tion or pressure on the individual nerves were commonly note ad

In these 53 cases practically all known procedures were employed with the exception of el ctropunc The author has given an outline of each of these cases with the operation and result and from them and the other cases pr nously reported in the literature it seems that ligation of the common caroud is by far the safest operation this fails one should be guiled by the condition of the optimery as to further operative procedures as cures have resulted after long period. If the nerve is not entirely gone and seems to be the atened the orbital operation "ommonly k own as Sattlers in which the uperior opthalms vein is ligated should be ttempted. This operation

whill yielding good results, exposes the patient to the danger from hemorrhage in some cases.

I the author's case, Hgation of the common carotid was followed by a complete cure, although the exophthalmos disappeared very slowly and was noticeable for more than four months after the operation.

RAR

Read J S Th Necrosity for Early Disaposis and Continuous Treatment in Congenital Syphilis 4 ck. Polist 9 6 xxxiii 44

The autho co cludes that the majority of these congenital cases are not receiving the full benefit of modern methods of diagnosis and therapy children of pare ta known to have or to have had syphilis should be onsidered he tic until proved otherwise. If no clinical signs are apparent blood examination should be regularly made. If there is a suspicion of a taint i the child and the serum is negative the parents should be Wassermannized, and if tests are negative the child should be treated and gain tested for often after a small mount of treatment a positive reaction will ppear. If there is in the parents any history f chancre many years back, a provocative injection of salvarsan or mercury should be given and often a negative serum will read positive at the next test

The author draws ttention to the various symptoms which in an unsuspected case should arrest the attention and call f a differential diagnosis exclud ing the presence of syphilis marasmus in a breast fed baby showing no signs of indigestion extensive pecling of the palms and soles a few weeks afte birth onychia a thinning of the eye brows in an infant a few months old alopecia and any eye le sions in the very young an unexplainable nephritis a peroxysmal hemoglobi urla a hardswollen testicle occuring under one year of age epiphysitis withi the first three months

As t treatment, the same persist at selected application of salvarsa mercury K. I. and tonics are recommended as in adults, and the treatment should not be discontinued as soo as symptoms disappear but the course should be guided by clinical OTTO M. ROTT signs, serologic and other tests.

Contes, G. M., and Ersner M. S. Veccin Treat ment of Chronic Supportative Otitis Media. Penn. H J 9 6 xlv. 585.

The a thors of this paper discuss the vaccine treatment of bronic running ears and report the results of series of so cases treated with utoge

nous vaccines of their wn preparation, the results of complement fixation tests | of the cases

Wassermann reactions, and 25 von Purquets. All of the 50 cases observed were inveterately chronic in type. The result obtained was 46 per cent of dry cars up t the time of writing the paper, which was several months after the last case had become dry Great stress is laid upo the technique of culture taking f vaccine preparation and plea made for close co-operation between the clinic and laboratory The techniqu used was t cleanse the middl car and canal as thoroughly as possible with cotton swabs or by suction fill the canal with alcohol f ten minutes remove and dry by evaporatin fr fifteen min tea. Then by t be inflation or by suction, a drop of pus was obtained on a ster fle platin in loop inserted through sterile speculum. Sometimes no growth was obtained evidently from too complet sterflusation

The authors bell ve that vaccine therapy will permane thy stop the discharge in a good many of these chrons are. Those showing much bony ne crosss, especially in the mastold, cholesteatoma and possibly labyrinth suppuration would probably not yield good results. They advise peglecting nothing in the w y of local treatment of the ear nose, and throat that m y be indicated but that vaccine should be given 'n connecti'n with all other accepted methods of treatment

The reasons f failure to btain dry ears are suggested as folk () Failure t obtain causati e rganism () nnecessary cont mination
(3) spoils g th accin i course of preparatio (4) incorrect dosage (5) possibly low antigenetic powers f the rganism and the contra-indications mentioned bove

A solution of the question of determini g the causat ve organism was attempted and me t axations done all of which negative result was obtained. The antigens used were polyvalent strains f several f the ordinary pus-producing micro-orga isms. In these same cases. Wasser manns were all negative and of 5 vo Pirquets, 3 we faintly positive and 4 trongly positive witho t local vidence of t berculoris in the en

egard t complement fixations, the thors co clud eliberthat () It is possible that only few free ambosept is are circulating in the blood in these cases () Bacteria in discharging cars are too it uated to stimulat antibody producti n. (3) A lowered body vitality m y ant gonize response t infection. (4) The rea may be so well walled if that absorption cannot take place. (5) The technique used may ot have been delicate enough

SURGERY OF THE NOSL, THROAT AND MOUTH

NOSE

Dean L. W: The Control of Hamorrhage in More Extensive Operations on the Nose and Jaws

Larysgoscope 19 6 xxvi 9 3

Before performing a major operation about the nose throat and jaws the auth r u utily lights one or more vessels in the next, then early in the operation the smaller peripheral viscal at solved with himostata. Usually some time lat r in the operation it is necessary to use, pressure himself to the operation himostangle by seeping.

In removing a superior maxilia r half n albif where it is necessary to invade the palat I or ton sillar region, the author advises the performance of a tracheotomy and packing the purport through the being removed just as the operation is comilled. An abundance of hot water and a large keeping cuttery should always be at han 1 fer the control of

deep hemorrhage and for seepages

he The most essential condition in the ntrol of hemorrhage in major operations is to have a pro- of assistants who have been associated with the operator in numerous operations, so that everything for the control of hemorrhage in the predicts and with precision.

The author has had no experien with the ligation of the large vessels on a his je of think the ligation on one side has, with the expirion of one case proved satisfactory.

One case proved satisfactory.

OTHER IN A R. IT.

Thomson S Malignant Disease of the Note or Accessory Sinuses Ad antages of Operating Through the Face. La t L d q 6 q 8

The author makes a plea for the performance of the Moure operation or lateral rhinotomy for maling ann timmon originating in the antronasid wall the roof of the nose in the antrum or in the spin and the advantages claimed for the precedure are

- 1 In all cases there is no mutilation or liftgure ment
- 2 Patients will readily consent to the operation 3 They are left with an intact roof to the mouth and no troublesome obturator is required as in the old operation of excision of the upper Jaw

4 It is much easier after a Moure operation to keep a direct lookout in the nose and its accessory envities for any suspicion of recurrence

- 5 Recurrences are more easily dealt with either through the nasal orifice or by repeating the lateral rikhnotomy and patients are less likely to olyect to this than to a further facial disfigurement
- 6 It can be extended to meet the rial | conditions met with or may be combined ith other operative steps for instance if it i found that the

disc see has die ji i invaded the orbit this cavity can be cli ared out through the same incision preserving the lower evold sarribing the cyclif necessary. It is need septiment to be removed if the growth houst septiment and the removed if the growth houst septiment in the antirum might be further lift with by an incision through the cannet costs, but the access to the antirum obtainably a Moure.

I if with by an incision through the canne fossa, but the access to the antrum obtained by a Moure operation cannot be improved upon. This may also been filled with the Denker operation. If the floor if the nose is found to be invalid the addition of a Rouge operation can be made.

I sternally the scar within a few months is so

slight is to be almost invisible

8 Hæmorrhage can be well controlled

o The front wall of the sphenoid is brought so well into the field that it is hardly one inch from the surfac.

The author describes the technique of the opera

The author describes the technique of the operation and reports two cases in which the Moure operation was performed.

In the first case endothelioms of the ethmoid and antrum there was no recurrence after five and one half years

In the second case epithelioma of the left maxil lary antrum there was no recurrence after three and one half years

- These cases demonstrated the following facts
 1 Both an endothelioma and a carcinoma in the
 nasal area are susceptible of satisfactory treatment
 by this method.
- 2 A history of some standing or exteriorization of the growth do not necessarily invalidate the good results
- 3 Dangerous duffi-ult and distiguring operations which were formerly tried can be superseded by modern methods which in the hands of experts are causer safer cause no disfigurement and promise a lasting cure.

 Ort M Rom

Vensey C. A The Diagnosis and Trentment of Inflammatory Affections of the Nasal Accessory Sinuses. J. Ophik & Ole Lary 101 9 6

After alluding to the importance of sinu disease as a causative factor in many gastro intestral affections as well as tozenilas aff cining other portions of the body the author considers the sinuses collectively and mentions the wilknown symptoms of headache tenderness, nasal obstruction and discharge dizziness and vertigo as well as aprosexia and neurastheme symptoms in general.

As to diagnostic methods the author mentions transillumination as one of the best methods of assisting n the di gnous. Other aids, as the ph rya goscope \ ray pu cturing and irrig ti g th n

trum, and the application of sucti to the nose are

favorably commented upon.

As to treatment I the acut condition, the author mentions the necessity of securing adequate drain age and ventilation, and this is secured by shrinking the nasal mucosa by the application of a weak solu tio of cocaine, instead of adrenain, as the latter is ant to produce secondary swollen condition greater than was previously present. After the membrane has been shrunken the author cleanses it with a normal sait solution it with mild alkaline solution followed by an application of a 5 per cent sol tion of arryrol and an oil spray. The patient is instructed to douche his nose freely with hot normal saline solution every hour or two and t tak deep inhalations every two or three hours of compound tincture of benzoin and menthol four ounces f the former and one druchm of the latter two tablespoons is are employed in one-half pint of boiling water General treatment with calomel. saline aspirin, and phenaceti is recommended.

The indication for the treatment of the chronicase is likewise, drainage, whether obtained by the contract! of battucting sepail deformation or hypertrophical turbinates. After drainage has been obtained irrigations are advised, and when theseprove futile, operative interference is justified. Not much faith is held by the thr in the benedical influence of autocenous yearons. Orro IL Rort

Berry H M Radiography in the Diagnosi of Discuses of th Accessory Nasai Sinuses. Arch Radiol & Electrotherap 9 6 xxi,

In radiographing the sinuses of the head the author makes use of the following positions () postero-anterior view (2) lateral view (3) oblique

view and (4) vertical view

In the majority of cases the postero-anterior and lateral views aloos will gi e the information de sired. The other views elucidat special points not made clear in the postero-anterior and lateral views. Stereoscopic pairs in postero-anterior and lateral positions often give additional information.

The bilgue view is made by first placing the patern and tube in the must position for making postero-enterior view and then displacing the tube internily about two inches. This projects the sphe noid sinus to one side of the nose displaces the petrous portion of the temporal bon clear of the antrum on one side, and brings the ethmoid of one side into fuller view. By making a second exposure with the tube displaced to the opposite side, comparison of the two sides may be made.

The vertical view is made by placing the patient chin over the edge of a table, the tube being placed above the vertex. This view above the sphenoidal

sinuses side by side.

Examination of the frontal annues reveals their extent laterally and ertically and the depth teroposteriorly. The thickness of their walls is also manifest and their accessibility through the nose. The presence and location of septa are determined These re important factors if a drainage operation is contemplated. The presence of air-cells in the crisis gall has a bearing a the possibility of meningeal infection from the frontal or thmodi ainuses. The determination of the thickness of the walls of the frontal sinus is important for these reasons

A thin posterior wall favors the spread of infection to the meninges
 A thin floo f wors the spread of infection to

the co tents of the orbit

3 A thick terior wall may mak operation very difficult or lead the urgeon t think the sinuses are absent

Evamination of the ethnoid cells gives informatio as t their size the total area covered by them and their relationship to the other coessory si uses. The latter point is important in considering the

The latter point is important in considering the likelihood if infection spreading from o sinus to another

Radiography of the maxillary inuses demminantes the filowing points (i) the size (2) relati 1 other sinuses (3) project on of tooth roots through the floor and (4) presence or beence of an al rolar recess

The third point is emportant as a likely aven e of infection in dental caries the fourth must be conindered when drainage operations are contemplated.

The facts t be determined rad ography of the sphenoidal sinus are its saze the thickness of its walls and t relationship t the sella furcica and the ontic biasm

The two latte point are very important ince the chief dangers suppuration of the sinus reextension to the meninges, to the pile nerve or thromboals to the interactually evenus amouse. Since the opti hisam is often in direct relationship to the oof it the sphenoidal sinus, the thickness if the bony wall is a very more if ctor in determining the likelihood of impileation of the optic erve in sphenoid infections. G. W. Gerra.

Arrowanith II. Malignant Hypernephroma of the Ethmoldal Region. Larragesce pc 9 6 xvvi 900

The author reports the case of colored male, by years of age, with history fobstructed I it ostifl and repeated att the of profuse bleeding from that side. The mass was removed by mare very profuse hem ritage ensuing necessitating tamponing A few days later the patient went home. The pathologist is report revealing the true nature of the growth, the patient was sent f and he reported that h had suffered several profuse tracks of homorrhage while t home.

Physical examination revealed a distinct mass in the right upper abdominal quadrant and enlarge ment of a number of superficial glands in that region many disseminated areas of consolidation in both lungs a right superclavicular mass the size of ben'egg. For the ext few weeks there was profuse bleeding. The left noutful was again filled with a mass and a complete exenteration was decaded upon. The left external carotid was ligated and the right supraclavicular mass removed. The nostril was exposed by a lateral rhinotomy after Moure's method and a frably yellowish mass was removed which had involved and district yed the entire left ethonoid region and the inner wall if the orbit. Bleeding was profuse and the patient died three hours after leaving the operating room.

The author states that this is the only cise in which the nose was involved in a metastati growth of hypernephroma although metastatic involvment of the laryax (one case by Menzel) and of toprue (one case by Conen) are mention. I

OTT MRT

THROAT

French T R The Tonsilloscope. \ 1 M J

The instruments needed for internal tonsilloscopy or the examination of the tonsil in situ are a leng tube speculum or tonsil microscope and a slender lamp which can be placed behind below or above the tonsil and buried within the vari us paces be tween the tissues so that its light is not directly exposed to the eye. The ton il microscope which is made in two sizes is a slinder tube or peculum about six inches long inside of which at the end of a sliding tube is a lens of from five to eight diopt is according to the visual needs of the examiner. The distal end of the microscope is beveled an l b aded and has an aperture the diameter of whi h is in one instrument one-quarter of an inch and in the other one-eighth by one quarter of an in h instrument with the largest aporture is intended for the examination of the free face of the tonsil and the capsule as well. That with the smaller aperture is intended for the examination of the capsule only

The lamp is of one candle power and is enclosed in a small metal case with a glass window at or hear its distal extremity. It is attached at an obtuse angle to an electric light shank which connects by a cable with a tungsten battery balanced in size and power to the candle power of the lamp. The tonsillar substain e.c. in however be more effectively transilluminated with a double, lamp which should be preferred in all examination in which the tonsill is large enough to hide the glas windows from view.

By this method of transilluminating the tonal lights up in much the same way as doer a stained glass window brilliantly, transilluminated from the opposite side. The outlet of the tonsil mi roscope is then applied to any an levers surface of the fur unnous tonsil not occupied by the lamp including a large part of the surface of the capule even if there are no adhesis us to the anterior pillar. Many of the conditions within the tonsil can in this way be seen directly. The meaning of the varieties and shades of coloring is a matter of interpretation

which has been developed from experimental color studies made in association with the anatomical histological and pathological findings

When the tonail is that of health or nearly so it is relatively translucent and permits a considerable in ight into its contents. When however it is the seat of disease it is less translucent in proportion presumably to the number and virulence of the bacteria in the pathogenic material present and the consequent inflammators reaction produced by them so that in extensive disease it is impossible to detect anything beyond collections of detritus and pus lying close to the surface.

Anoth r instrument which the author calls the external tonsilloscope is used for the examination of exploratory sections removed from the tonsil at the beginning of operations and for the study of the tonsil as a whole or in part after opera tions. It consists of a simple microscope on a light screen and a powerful electric lamp suspended together from a crane The object in their suspen sion 1 to make it possible to conduct the examina tion without a break in surgical cleanliness. The lens in the microscope has a magnifying power of six diameters. It is fitted into the proximal end of the tube of the microscope and has an adjustable The mi roscope tube tapers to a size at the di tal end whi h can be readily covered by a section or the whole of the tonsil. The specimen is caught upon a hook at the distal end and left in position f r lessurely study. The lamp is the Nernst of 350 can lle nower

The former procedure internal tonsilloscopy is of more practical agraincance

The following classification of the conditions found in the tonsils is offered

I The tonsil of health

Functional stimulation or mild disease the doubtful class

3 Superficial abscesses

4 Apparently active or large foca of detritus and pus occupying restricted areas.

5 Considerable general disease

6 Extensive general disease

The picture of the tonsils as seen through the microscope in the above classifications are then given as follows

It he color of a tonsil in health is warm amber but the passage of light through a time deg of a tonsil or through a very small tonsil of health even in an adult produces a color more like that of rock candy. In the tonsil microscope small arteries are seen cour ing upon the surface and to some extent in the stroma while here and there in the substance of the gland appear small round red spots like flies in amber.

2 In the doubtful lass functional stimulation or mild disease there is a diparture from the normal indicated either by a uniform peak-ambe coloring involving the citie tonsilo by hypersemic blushes coloring small areas of the miler field.

co ering small areas of the moer field 3 In the class, uperi al bacesses, bind abscesses are seen just under or near the epithelium on the free face of the tonsil which transilluminate as dark or black discs according to their proximity to the surface the pearer the surface the darker the ahade. In the tonsil microscope abscess formations when present may also be found directly under the capsule.

4. The class characterized by apparently active or large foci of detritus and pus occupying restricted areas. The prominent feature found upon examination of this group, with the tonsil microscope and transillumination is that the hyperemia is in more or less sharply defined areas set in a field which may not be far removed from the colori g of

the tonsil in health.

5 In the fifth class in which there is considerable general disease there is uniform though comparatively light hypersemia indicating that there is multe a number of collections of detritus scattered throughout the tonall, but probably no pus.

6 The sixth class is marked by extensive general disease, which implies the honeycombing of the crypts and the substance of the tonsils with detritus and pus. The coloring in transillumination is uniform and of the deepest shade seen in the tonsils, and always corresponds to that of the anterior pillar

The following conclusions have been offered as a result of a study of 666 tonsils in and from 313 operations upon children and the at dy of tomalia in sits in a large number of youths and adults

1 All enlarged tonsils in subjects above the age of eight years are diseased.

Enlarged tonsils in subjects below the age of eight years may or may not be diseased, and whether they are r not can be determined only by examinatio with the tonsilloscope.

The torsils in subjects above the age of childhood are often, and without much doubt oftener than we now know, the seats of foci capable under certain conditions of producing local and systemic infections.

In many bjects with torsils in classes 2 3 and 5 it has been proven that they are the source of systemic infection, and total en cleation bolds out the only hope of complete and permanent relief.

5. Tourils which are the seat of extreme disease and which are, therefore, seen to be excessively hyperemic, bleed freely when cut into

6 The inner wall of a peritonsillar abocess can be located and mapped out with ease. OTTO M ROTT

Adams, E. Sarcoms of the Tonell. Am Med 0 6 zl. 320

The case reported is that f woman aged 58 who had a small ulceration about the size of a dime on the left tonsil. The tonsil was movable but the cervical glands anterio to the sternomastold muscle were enlarged. The clinical diagnosis of surcoma was made and the high-frequency current was polled daily both to the tonal locally and external ly to the glands but with no effect. At the same time Coley's serum was used the injections having been made in the gluteal region, subcutaneously The dose at first was ne minim but it was pushed to 15 minims when the patient had a severe reaction. There was o influence n the growth, however consequently radium therapy was used, but the only result was severe radium burn. The tonsil then was removed by means of a snare and exam med microscopically when a diagnosis of round cell sarcoma was made,

Radium was again used but in spite of this the glands in the eck and avilla increased and later there was evidence of pulmonary metastasis with sudden death evid the from pulmonary em bollam Orm M Rorr

Kenyon, E. L. nd Kradwell W T A Study of th Physicomechanical Function f the Faucial Tonad Ill sens M J o 6 ru 416.

The autho study exulted in the following concludons I The tonni serves as an absolutely eccessary

factor in providing palatolglossus musci

The function of the tonail with reference to the palatopharyngeus is t afford support and protec tion of great importance to its normality of action

hann I for the ction of the

3 Tonsillect my serves t destroy not merely possible lymphat c function of the tonail but also to either disturb or destroy an important physicome chanical function, on which is capable of being clearly aderstood

4 More or less impairment of the action of the depressor palatal muscles must occur in practically all cases foll wing tomillectomy regardless of the delicacy of operative technique or the particular form of operative procedure dopted but delicacy of procedure and method of operation are not of course to be considered unimportant

5 T consider the present operation of tonsil lectomy as a final settlement of the operative approach to the tonsil is premature and erroneous The whole tonsil q estion requires further anatom ical, pathological, and operative study in order if possible to readjust the operatipproach to the rgan to the new kn wledge which is accumulating Отто М Котт

Forrington P M Toneillectomy According t the Studer Technique. Semi M J 0 6 i 456

The author regards properly performed Sluder operation as the simplest safest and best method of performing tonnillectomy H regards tonsillec t my as a bospital procedure t be performed in the morning after the patient has been thoroughly examined by an internist and properly prepared for general anesthesia.

With the patient on his back, under ether anesthesia the operator removes the tonall with the Slud er instrument and fills the tondillar foesa with a gauge pad. After inspection of the tonall to see if it is intact, he removes the gauze sponge, inspects the fossa stops all bleeding with clamps who h he allows to remain on for a minute and proceeds with the other tonsil In a series of 175 cases operated upon by this method the author ha f only 5 failures all of whom were adults ELL J P TTERS Y

Dupuy II : A Study of Five Hundred Tonall Enucleations with the Beck Pierce Tonsillec tome South M J to 6

The author claims many advantages for tonsilled tomy performed with the Beck I ierce tonsillectome basing his opinion on data obtained in five hun fred consecutive cases operated upon with this instrument by a modified Sluder technique Among the advantages he claims that enucleation can be quickly performed danger of hemorrhage is mini mized there is less traumatism and local rea tion than by other methods though he admits these advantages are obtained in operations on hildren under the age of ten years and that this method is not ideal in operating upon adults

As to the technique, the tonsil is lifted unward into the supratonsillar region and gently pushed through the ring of the tonsillectome with the index finger The mass is then seized with a grasping forceps meanwhile keeping the index finger against the tonsil and the wire loop slowly drawn thus enucleating the tonsil with a thin layer of capsule and leaving the greater part of the capsule in the fossa as a protective lining

ILLEN | LATTERSON

Escalada C. Fractures of the Larynx : Fra t ras d la larnira) P med hg t

The author has made an elaborate study of laryn geal fractures. In some cases the mechinism of a laryngeal fracture is evident and does not call for discussion. In others however the clinical manifestations admit of different interpretations Es calada has made six series of experiments on the cadaver using anteroposterior pressure upon the thyroid the cricoid, and the laryngeal conjunctive then repeating this series using transverse pressure He found in general that a pressure of 55 to 80 kilograms was necessary to fracture the larynx but that the force varied with the age of the subject and the degree of ossification

In a case of fractured lary nx the treatment in general will be confined to prevention of asphyxia tion pending intervention by a specialist. Tra heot omy is recommended for the pre ention of recur ren'e of asphyxia but som recommend this as a precautionary procedure to obviate the accidents which might occur W A BREKNAN

MOTITH

Merritt A H 1 The Rocatgen Ray in Dental Prac tice 4m J Rosnigenol 9 6 iii 264

The author discusses the use of the roentgen ray in the following conditions (1) periapical infections (2) pyorrhœa alveolaris (3) missing and impacted tecth (a) facial neuralgia

r Penanical infection When a tooth loses its vitality it is only a question of time when it becomes infected. The acuteness or chronicity of the sympt ms of this infection depend upon the number and virulence of the organisms engaged. If the infation lapses into the chronic state, the pain subsides and the patient is usually unconscious of its presente. A discharging sinus may be present or a blind abscess may surround the root of the tooth, Differentiation between these two conditions can not be made by the roengten ray nor is the seventy of the infection disclosed by roentgen examination Every non vital tooth should have the pulp removed the root-anal sternized and filled to the end in order to prevent trouble which is certain to come unless this is done. If abscess is already present in addition to this the abscess should be opened through the alveolar process curretted, packed with sterile gauge and allowed to heal from the bottom If the end of a root extends into the cavity it should be amoutated Teeth treated in this manner are not a menace to health and should not be indiscriminately extracted. Where extraction is necessary it is advisable to first procure cultures for autogenous vaccines as the secondary constitutional symptoms do not always clear up with the removal of the exciting cause

2 Pyorrhora alveolaris The amount of destruction of bone in this condition is not always correctly shown by roentgen examination. If the necrosis occurs on the labial or lingual surfaces of the tooth it will not be visible on the roentgeno-If it occurs on the lateral surfaces only the condition may appear to be worse than it really is.

3 In missing or impacted teeth the roentgen ray is indispensable not only to demonstrate the presence or absence but also the relative position of the teeth in question

4 Facial neuralgia. If this trouble is caused by pulp nodules, or by enlargement of teeth roots (hypercementosis) the roentgen ray is of great diagnostic value. The author lays great stress on the fact that it is seldom necessary to ray the en tire mouth if proper inspection is made previously Pyorrhora is easily identified while penapical infections always occur in non vital teeth. The only thing then left to ray are malposed teeth which are usually molars G W CRIER

Actually Shot from Guns

Puffed Wheat and Puffed Rice are actually shot from guns. This is done to explode every food cell. The result is easy complete digestion. Every atom of the whole grain feeds.

This is the process invented by Prof A P Anderson formerly of Columbia University

The grains are sealed in guns The guns are revolved for sixty minutes in a heat of 550 degrees

This changes to steam the trifle of moisture which lies within each food cell. And a grain of wheat contains 125 000 000 of them

When the guns are shot that steam explodes Every food cell is thus blasted to pieces The grains are puffed to bubbles eight times normal size

These are delicious whole-grain food airy flaky tonsted crisp But we talk them to you because they mean whole grains made wholly digestible. And that was never done before

SAN FRANCISCO, CAL SEATTLE, WASH

After prolonged lactation a mother's milk usually decreases in quantity and nourishment. It is then that a properly prepared liquid extract of malt and hops would not only increase the volume of breast milk but the amount of its fat content. But to accomplish this, it must be a real extract of malt and hops and not a cheap imitation

Malt Jutrine

is the recognized standard of medicinal malt preparations, and is prescribed by eminent physicians for the mother and child at the nursing period. It is made of the choicest barley malt and Saazer hops and contains all the soluble substances of these two materials.

Newer Blood Tests

for Rheumatism, Arthritis, Gout, Nephritis, Uremia and Diabetes

In diabetes it is desirable to determine the sugar content in the blood, since this may be high, while the glycosuria may be low owing to in efficient kidney function. In diabetes with acidosis the curbondioxide determination is useful since any considerable increase indicates a grave condition.

For differential diagnosis between gout arthritis and rheumatism the estimation of uric acid and non protein nitrogen in the blood is of assist ance. In gout uric acid only is increased in arthritis both the uric acid and the total non-protein nitrogen are high while in rheumatism both are normal. More detailed information on request

DISEASES

OF THE

Kıdneys, Ureters

AND

Bladder

BY

HOWARD A KELLY, M D

In Collaboration With

CURTISF BURNAM, M D

No other work on urological problems has been written which covers the subject from the standpoint of the female as well as the male.

This work is to the field of unnary diseases what Dr. Kelly a gynecological works are to the field of female diseases—the most important and valuable contributions of the kind.

The methods of the authors are based upon careful analyses of several thou sand cases personally handled by them during their long connection with the Johns Hopkins University and Hospital.

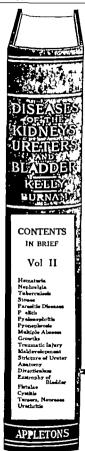

Greatest attention is paid to the common diseases rather than to those which are rarely presented to the general practitioner

AMERICAN ATLAS OF

STEREOROENTGENOLOGY

Edited and Published Under the Sole Asspices of THE NEW YORK ROENTGEN SOCIETY

Editors Leopold Jaches, M. D., H. O. Imbeden M. D., William H. Stewart, M. D.
With exception and extraording threather the veril

Publisher & Announcement

HE foregoing announcement marks another mile post in the dvancement of medicine and surgery

The membership roll of the New York Roestgen Society which as an organization has taken full command of this new enterprise is almost yonovprous with the muster roll of those brave spirits, throughout the world, who have drawn from this new and often fatally eracting sedence its protoundest secrets, hence we believe the American Atlas of Stereoreentgenology will be at once exceeded position among the forement and most import at clinical publications of the safe.

ITS SCOPE. The scope of this publication will be CLINICAL in the broadest sense eluddating Anatomy Physiology Morphology Organology and Pathology in the living subject in a more practical and graphic manner than ever before attempted

It will give more intimate view of structure and organs in the living body more clearly define their relations to one another and to function, both under normal and pathological conditions, and thus tend to a clearer meaning of symptoms and signs and finally render the subject of Clinical Diagnosis less difficult.

ITS ILLUSTRATIONS. The illustrations will be almost exclusively Stereoroentgenograms—double Roentgenograms taken from different angles at almost the same natural

ITS TEXT. The descriptive text will in each instance begin with the earliest procurably history of the case and if low it step by step until it renches the Stereoroentgro Laboraty and where possible, verified in the operating post mortem room thus affording the greatest opportunity for clinical comparison.

ITS FORM. The American Atlas of Stereoroentgroology will appear quarterly as loose leaded journal, and each number will be provided with a neatly labeled case or revergiving it the appearance of a book or volume which will mak. It attractive when placed on the book shelf. The size of this case will be about 7 of nickes.

Each ambet will record about eight important cases and the dvantages of this form of publication are manifold incilitating the st dy of each case and it. Stereograms separately the correlation of cases for comparison and final grouping of the subject matter according to subjects or branches.

according to subjects or transmer.

AS A JOURNAL. From Issue to issue it will contain editorial comment and clinical articles illustrated by this incomparable method, that will keep pace with the latest thought and achievement in these newer methods of disgnostic.

AS AN ATLAS. From year to year it will add to the working library one complete volume, in four parts, of graphically demonstrated clinkal material, that the entire world has bee drawn upon to provide and which are recorded because of their extreme clinical value.

THE MATERIAL AND PRICE. The publisher frankly admit that the publication of this work is made possible through the generous co-operation of the members of the New York Koentgen Society in placing their records and priceies collections subject to equit it only the editors and that this co-operation makes it possible for the publishers to find the price of the Atlas which the easy reach of all its, et no bother samually

New 3rd Edition

Just Ready

Thoroughly Revised

INFECTIONS OF THE HAND

A GUIDE TO THE SURGICAL TREATMENT OF ACUTE AND CHRONIC SUPPURATIVE PROCESSES IN THE FINGERS HAND AND FOREARM

By ALLEN B KANAVEL, M D

Assistant Professor of S. gery N. ribnestern U. J. ersity. Medical Department; Attends g. S. geo. Wesley and Cook Cou. ty. Hospitals. Ch. cago.

Octavo, 498 pages, with 161 engravings Cloth, \$3 75 net

THE importance of this work to all surgeons is demonstrated by the fact that it has passed so quickly through two large editions. The urgent demand for a third edition has given the author an opportunity to enhance the value of his monograph by a thorough revision and by the addition of new material in text and illustrations.

The enormou economic significance of infections of the hand is coming to be universally recognized. There is probably no other class of cases where malpractice is more common or unfortunate results of treatment more frequent. Therefore the subject of this book is of the greatest interest and importance to every surgeon and general practitioner.

The surgeon who does casualty work or has charge of industrial accidents will find this work invaluable and many deformed hands might be prevented if every practitioner were tamiliar with the importance of this subject and with the complete manner in which this book handles it

Any physician who carefully follows kanavel will have his conception of the subject completely clarified. The various chapters on treatment of different conditions are very full the technique is well described and the after treatment is carefully given. Following each chapter a definite complete resume is given which will be found most helpful

The 5 Ligation of splenic pedicle. (Donald C Bullour)

SURGERY, GYNECOLOGY AND OBSTETRICS

AN INTERNATIONAL MAGAZINE PUBLISHED MONTHLY

LOTTAL ZZIII

JLL\ 1916

NUMBER I

THE TECHNIQUE OF SPLENECTOMY

By DONALD C. BALFOLR M.D. FACS. Room TER MISSISSITA

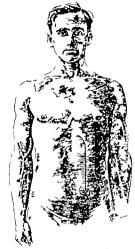

THE more trequent recognition of certain chronic disorders of the blood particularly plants anoma hemoly its jaundice and permicious anima and the therapeutic value of splenectomy in these and other diseases have recently greatly extended the indication, for splenectomy and suggested some observations on the technique of the operation. In our experience (especially in those cases in which technical difficulties are encountered) the operation has been facilitated by following a routine plan and by the precision with which the detail of such a plan are carried out.

Through a left Bevan incision (Fig. 1) its length depending on the size of the splient the abdomen is explored. The suggestive frequency with which jaundice attacks of opgastic pain simulating biliary collectricosis and gall stones occur in many of the diseases for which splenectomy is advocated necessitates an accurate record of the condition of the liver gall bladder and bile passages. Such observations will ultimately possess specific value in the elucidation of the obscure but unquestioned intimate relation ship between the spleen and the liver.

The dislocation of the spleen from its position against the disphragm and the left kidney (Fig. 2) should be the first step in the actual removal of the organ. The separation of the disphragmatic adhesion can usually be safely accomplished by the finger. If it is found that the adhesion have acquired blood vessels of sufficient size to require ligation it i then even preferable in mo teases to postpone such ligation (unless the vessels be reasonably accesable) until the pleen has been removed the bleeding being temporially controlled by a gauze pack described later In an occasional case however adhesions cannot be stripped with saicty and they must be divided between long curved forceps care being taken to engage only the adhesions in the clamps. Hartmann and other have advised that the operation be abandoned when these adhesions appear formidable However we have not recently found such conditions to be prohibitive to splenectomy although in some cases absolute hymostasi has been secured with considerable effort

Immediately the spleen has been dislocated a long hot abdominal pack is efficiently ar ranged in the space formerly occupied by the spleen until the entire area with which the organ has been in apposition is under firm pressure by the gauze (Fig. 3) This accomplishes two purposes First and most im portant the oozing surfaces are compressed and as the bleeding is usually venous it is controlled without subsequent ligation if the pack (a point emphasized by W. J. Mayo) is left undisturbed until the actual operation is completed. Second an excellent support is provided for the safe manipulation and mobilization of the organ the division of adhesions and ligation of the main pedicle

-

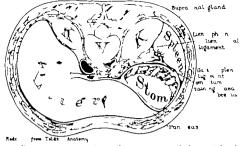

I'm Bevan incision as adapted for splenectomy

The spleen having been elevated in this manner its further connections are the main splenic pedicle with its pentoneal investment (the henorenal ligament) the gastrosplenic omentum and in splenomegaly of long stand various adventitious adhesions. The most satisfa tory isolation and treatment of the splenic pedicle is obtained by the prelim inary division of the accessory adhesions as well as the peritoneal attachments and reflections The gastrosplenic omentum should first be divided in sections as close as possible to the spleen, between ligatures. The only named vessels encountered are the vasa brevia, which arise from the splenic artery at variable points, pass to the greater curvature of the stomach, in this peritoneal fold and finally anastomose with the left eastro-epiploic. In dealing with the upper edge of this gastrosplenic omentum at must be remembered that here the fundus of the stomach is normally in very close apposition to the spleen. It is necessary therefore always to determine the exact relationship and protect the stomach from injury in its separation from the spleen. In an earlier experience I accidentally included in a clamp and excised a small area of the wall of the stomach the resultant opening however being readily closed without post-operative complication At the lower pole of the spleen there is an occasional fibrous attachment derived from the phrenocolic ligament, which with the other adhesions should be separately ligated

The spleen may now be further mobilized by careful dissection of the pentoneal and tibrous coverings of the splenic pedicle. The localization of the tail of the pancreas is the important feature of this mobilization, and as the relationship of the organ is not constant it is necessary to inspect it in all cases. In some instances the tall is short lying against the renal surface of the spleen on the poste nor aspect of the pedicle and it may be fitted so closely into the hilus of the spleen as to have acquired a concave edge In other cases the tail is attenuated it is in front of the splenic vessels and in contact with the gastric surface while often it does not extend into the operative field

Figure 4 shows the spleen turned turtle pancreas to the splenic pedicle. It is quite obvious that such a pedicle would not be ligated without including a portion of the pancreas. Figure 5 (frontispiece) shows that with the reflection of the henophrenic ligament a better exposure is obtained of the tail of the pancreas that it can be detached from its original position by dissection and allowed to drop back from the hilus of the spleen

Therefore after such dissection the spleme pedicle consists, from a surgical standpoint of the splemic artery and its veins. The artery in some instances has divided before reaching the hilus of the splem, although it often continues as a single trunk well into the hilus

Lik. Diagrammat repredictation ith import tork I latio with pl

while the vein are alway in two or more branche. The latter do not bear a fixed position as regard, the arterial trunks lying in first in some in tances and behind in other. They are always distinctly larger than the artery itself and their extreme frability multi-always be considered. The arrangement of the vessels of the pedicle 1 fan shaped a in Fig. 5 or 6, the breadth varying in different cases.

At this point it is possible to decide whether it is best to treat the pedicle en masse (Fig. 6) or to ligate it in section. (Fig. 5 frontispiece) The latter method is to be preferred and the dissection of the pedicle is usually mest advantageously carried out on its posterior aspect with the spleen tracted toward the midline. The extent to which the pleen can be liftedout of the abdomen by careful traction is surprising, if following the division of the

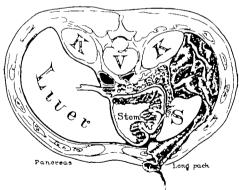

Fig 3 Position f the gaur pa k

Fig. 4. Porterior surface of splem exposed, showing tail of pancress which her in the splemic pedicle posterior to vessels. The pancress should be dissected from its postion before clampor figurors: re-applied.

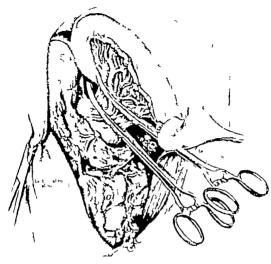

peritoneal and fibrous investments of the pedicle certain of the lateral venous trunks are separately isolated and divided between heatures (Fig. 5 frontispiece) It should again be emphasized that caution must be exercised in the degree of traction to which the pedicle is subjected and in the dissection of these vens. It is chiefly because of the normal tortuosity of the splenic artery that this elongation of the pedicle is possible and thus facilitates its secure ligation We have recognized the advisability of first securing where it is possible the arterial supply so that the spleen may partially empty itself of its contained blood through the unclamped veins before these are ligated.

If on account of the arrangement of the vens and arternal branches, higation in sections is not advisable ligation es masse by the two-clamp method, will prove a satisfactory and safe method. Two curved clamps

are arranged on the pedicle with a third clamp on the splene side to control back bleeding i and the spleen is removed. A double trand of No 2 plain catgut is tied with moderate tension in the crushed line of the tuner clamp as a partial control, and a second strand is transfixed below the distal forceps as the actual control.

Having made certain by either of these methods that the pedicle is securely ligated the large harnostatic pack is removed the newly exposed surfaces inspected, any oaning points being separately secured by hin cat gut on a needle and absolute hemostasis assured.

The disease or condition for which splence tony is done governs largely the technical difficulties and risk of the operation. I have found for example that in permicious anomias the removal of the spleen can be accomplished with comparative ease and safety. Although

I ig 6. I entoneal attachments separated mobilizing piece and per mitting application of clamps. I edicle t. be divided at d. tted lin

enlargement of the organ has been present in those cases in which we have advocated surgical treatment, adhesions are few and usually insignificant. The pedicle is as a rule small and in a relatively small percent age is its treatment complicated by the relationship of the pancreas. Furthermore the risk of the operation in this disease can be minimized by intelligent pre-operative treatment and observation as well as by the careful selection of the cases There must be a rational basis upon which splenectomy in pernicious anemia is advocated, as well as strict recognition of the limits of operative Splenectomy is definitely contra indicated during an acute crisis or in a period when the patient shows a steady decrease in hæmoglobin and red blood-cells or when

mental torpor cord changes and cedema mark the terminal stages of the disease. Repeat ed transfusions from a suitable donor will frequently carry the patient through most critical exacerbations of the disease and the proper interpretation of the reaction following transfusion is essential. Further it is important that a satisfactory donor be available after operation.

In splenic anomia splenectomy is associated with a higher operative risk and greater technical difficulties than it is in any of the more common diseases of the spleen. In the cases I have seen the spleen has been usually of large size the vessels very frable and adhesions occasionally troublesome. Patients in the late stages of the disease are prone to develop fever assites carribotic liver or severe

anama, which conditions contribute to the seriousness of the operation. The only in stance in which I thought it madvisable to attempt splenectomy was in splenic anemia with great sacities, attrophic cirrhouss, and aneurismal splenic vessels. The friability of the vens in this disease was especially demonstrated in a baby 22 months old upon whom I performed splenectomy for typical splenic anemia of the adult type.

The operation in hemolytic Jaundice is of relatively little risk and there has been particular difficulty in the removal of the spleen, although the organ is occasionally very large. It is however most important to avoid splenectomy during an exacerbation of the symptoms. Of the cases I have seen of this disease the only operative death occurred in a patient in whom I falled to realize the import of a subacute and subsiding achol uncertain.

In those cases of cirrhosis of the liver associated with splenomegaly in which splen ectomy is to be considered the splen is often firmly adherent, and this fact together with the poor general condution of the patient makes the operation rather hazardous. Nevertheless, in the cases we have selected for operation there has been no operative mortality, and in two cases of my own most triking benefit has thus fat followed the removal of the spleen

In the rarer conditions such as syphilitic spleen and idlopathic splenomegals the operation itself is not of great risk. It has been interesting to note the result of splenocetomy in two cases of splenomegals with specific history and positive Wassermann. In both of these it had been previously possible to obtain a negative Wassermann by salvarsan but it would become positive on discontinuing the treatment. Since splenectomy the Wassermann by remained negative.

Wasermann has remained negative From my own experience I have found that the features to be emphasized in the tech nique of splenectomy are (i) the abdominal exploration, (i) the dislocation of the spleen (3) the use of a hot gauze pack (4) the protection of stomach and pancreas from injury (5) the preliminary lightion of adhesion and (6) the treatment of the splenic pedic le-

THE ETIOLOGY OF UTERINE PROLAPSE AND CYSTOCELE!

By GIBBON FITZGIBBON M.D. FRCPI DUBLIN IRELAND
6 necologist Royal City of Dublia Hose tal

THE subject of uterine prolapse and cystocele is one upon which there has been a great deal written and still new operations are constantly being described involving the removal of the uterus the distortion of parts and even the complete obliteration of the genital tract There is surely some method by which the structures that normally support the uterus and vaging can be restored to functional activity and at the same time leave the organs which have to be supported intact in approximately normal positions and possibly canable of functionating - some operation which can be adopted as the all around basis for the surgical cure of the condition

The majority of the cases of prolapse are met in women who have borne children. The prolapse is the result of damage caused by the passage of the foctus through the polivis. In this act some structure which before labor was capable of supporting the uterus must be rendered incapable of doing so subsequently. The probability is that it is the same structure which is damaged in all or almost all the cases.

Prolapse occurring in nulliparous women is probably due to the same defective structures but there has not been any cause of laceration and therefore the prolapse must be due to some congenital defect of the supporting structures. This places these cases in a different category as the supporting structures even though not injured are incapable of supporting the uterus and any operation is subject to the doubt as to whether the tissues can be made capable of doing what they have already proved incapable of

That the perneum and that part of the levator an muscles which is torn with the perneum have no part in the support of the uterus is made evident by the fact that these structures may be extensively lacerated and this even when of long standing has no evident effect upon the level of the uterus. Lacerations

of these structures lead to the condition of rectocele. In which the rectum bulges forward and downward into the vulva stretching the posterior vaginal will in its lower half but leaving the upper hilf and the potention for rectocele is completely cured by a platic operation upon the levator ani muscles and the perineum and the restoration of the pirts to their normal condition.

On the other hand, there are numerous cases of prolapse of the uterus where the cervix comes down to the vulva or even the uterus is completely extruded, yet the perincum and levator ani are intact showing that some other structure is responsible for their maintenance and that the levator ani muscles are not capable of replacing this support. The c facts definitely prove that the structures which support the lower half of the posterior vaginal wall have no part in the support of the uterus and therefore may be excluded in looking for the cause of prolapse of the uterus which must do damig, to some structures above the level of the levator muscles.

The structure which is next met with in the pelvis above the levator muscles is the visiceral or endopelvic layer of pelvic fascia and as I believe this is the main if not the sole support of the uterus and bladder I wish to give a very full description of its attachments and relations

The pelvic fascia as shown by Cunningham (1) is a direct continuation of the abdominal fascia which is easily demonstrated as a continuous sheet lining the interior of the abdominal cavity and placed between the muscles and the peritoneum. The relative position of the pelvic fascia is identical and the viscoral layer passes, inward from the pelvic walls upon the upper surface of the levator ani and forms a complete fascial diaphragm to close the pelvic outlet. It springs in part from the back of the symphysis and the public ramus about the level of the junction of the lower

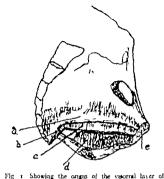

and middle thirds of the symphysis. From here it runs under the bladder and forms the true anterior ligaments of the bladder. It surrounds the urethra and is intimately connected with the base of the bladder upward along the walls of which it sends numerous fibers as well as others downward along the urethra. The fascia passing under the base of the bladder is closely connected with the anterior wall of the vagina and is continued backward to be attached to the supravaginal cervix where it helps to form the anterior vaginal fornix This part of the fascia is very definite and usually described as the anterior true ligament of the bladder brids the bladder and urethra firmly to the posterior wall of the symphysis.

The next part of the pelvic fascia springs from the public ramus and the white line hrat at the level of the too of the obturator fora men and from the inner surface of the ischial spine it runs inward above the levator and muscles toward the varina, bladder cervix, and rectum and divides into the vesical vesicovaginal, rectovaginal and rectal layers The posterior part of the fascia here surrounds the rectum, and follows its walls as the rectal layer at the same time giving some support to the upper part of the posterior varinal wall where that is in relation to the anterior wall of the rectum, and this part constitutes the rectovagual layer The anterior portion of this fascia is stronger and thicker than the rectal portion, and constitutes the vesicovaginal layer As it runs inward toward the viscera it divides into numerous layers and becomes intermixed with loose connective tissue, which makes the demonstration of the whole fascia almost impossible close to the viscers. Nevertheless, the continuity can be shown and the different layers followed to lose themselves upon the walls of the viscera or to join the fascia of the other side. It is connected to the sides of the bladder and continuous with the anterior fibers of the fascia which pass under the base of the bladder passes across the pelvis between the anterior vaginal wall and the base of the bladder and is attached to the cervix uterl and the lateral vacinal fornices, above which it passes to reach the cervix and to become continuous with the

rectovagual laver between the posterior vagi nal fornix and the rectum and below the posterior cul-de-sac of peritoneum. The at tachment of the fascia to the viscera is shown by Cunningham (a) in a dissection on the male and the same relations of the fascia to the viscera exists in the female, the vagua and the cervix uteri taking the place of the prostate

In the region of the lateral vaginal fornices and the sides of the cervix, where the uterine vessels approach the uterus there is a very marked increase in the amount of fibrous tissue in which the uterine vessels run, this extra fibrous tissue forms a distinct fan shaped band lying between the lateral vaginal formy and the side of the cervix in the plane This band has been of the broad beament described by Mackenrodt (3) as the transverse ligament of the cervix. It is part of the pelvic fascia and plays a part in the support of the uterus and vagina with the rest of the fascia from which it should not be dissociated. Hart (4) refers to this as the loose fatless tustue o 8 inches thick with abundant blood vessels and lymphatics surrounding the lower portion of the uterus and upper portion of the vagina and says it was first described by Virchow and called the perametric tissue and is clearly shown by Freund in sections at the level of the supravaginal portion of the cervix.

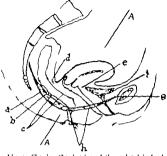

This intermediate part of the endopelvic fascia between the hyaments of the bladder and the rectal layer is usually described as if it merely formed a sheet above the levator ani muscles, and the rectovaginal and vesicovaginal layers as though they passed between the viscera just above the fibers of the muscle. wherens the fascie is at a higher level in this part than the levator muscle. In section through the female pelvis this part of the fascis does not show up distinctly because the fascia is not in a distinct sheet and when the fibers are divided they retract in the loose tissue and do not show on the surface consequently the fascia is omitted in the region of the vaginal fornices and cervix, and that part which can be demonstrated as a sheet by dissections just above the levator muscles is depicted as the whole of the vericovaginal

pel is fascia from the inner wall of the pel is with the levator ani muscle arism, just below it. a Visceral layer of the pelvic fascia springing from white line b cocypeus, c levator ani d parietal layer of pelvic fascia. s pub c bone.

layer Where the fasca springs from the pelvic wall it can be seen as a distinct sheet but where it comes into relation with the viscera it loses the character of a sheet and divides up into various layers. The necessity for this is obvious when the dilatation which must occur during parturntion is considered. If the fasca remained a single sheet where it is pieced by the cervix and the vagina the aperture would be incapable of dilatation whereas by means of the fascal there separating and running at different levels the supporting power is not diminished and the dilatation of the aperture is possible.

The description of the fascia in Cunning ham's Anatomy together with his diagrams makes this perfectly clear. He deals with the fascia chiefly in the male subject and refers to this description when describing the fascia in the female. He says the rectum below the rectovaginal pouch of perioneum is in apposition with the posterior wall of the vagina a layer of pelvic fascia the rectovaginal alone intervening. His illustrations show this part of the fascia distinctly as well as the vesicovaginal layer except that the prostate is shown instead of the vagina.

If g > Showing the d vision of the endopelive finds into the vains of lan ris. connection with the licera, the abu dance of fiscia in the region of the vaginal formers and cervive tuten and under the base of the bindder along the analysis of the bindder and the analysis of rectal layer of recta single of rectal layer of recta single selection and layer events outpind layer f version against layer when the single selection in Fig. 3.

and he says the rectoprostatic fascia is called the rectovagual and the vesicoprostatic fascia the vesicovaginal Cunningham (s) also describes the fascia in connection with the female pelvis as the endopelvic fascia and divides it into an upper portion attached to the upper parts of the vagina and cervix and in front of these passing between the vaging and bladder to reach the mesial plane and lose itself upon the walls of the viscera, while the lower laver is that part of the fascia which follows the levator ani muscles and is inserted into the penneal body The relation of the viscera to the pelvic fascia is such that the bladder rests on the upper surface of the fascia in front. The vagina owing to the backward and upward direction of its axis passes through the plane of the fascia at an acute angle so that its anterior wall which is facing upward and forward is in relation to the under surface of the fascia at that part upon which the bladder rests Behind this the fascia passes obliquely across the sides of the varinal fornices and over the top of them being attached to the cervix, and the posterior vaginal wall being longer than the anterior is continued back so as to pass

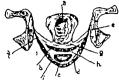

Fig. 3. Coronal section through pelvis showing the division of the vinceral layer of pelvic fascia into layers in relation t the vincera. Uterna, vagna, rectum, a levator and, obturator internos f vinceral pelvic fascia, e vendorvaninal layer à rectovaginal layer rectal layer.

through the plane of the fascia behind the cervix. In this way the vagna is almost altogether below the plane of the fascia and has its attachment by fibers to the under surface. At the same time the fascia sends numerous fibers to all parts of the vaginal wall.

The cervix uteri definitely passes through the fasca, the vaginal portion being below the supravaginal portion above the plane of the fascia but owing to the oblique direction of the axis of the uterus running forward there is a greater attachment of the fascia in front of the plane of the broad ligaments than behind so that the vesicovaginal layer practically forms a sling across the pelvis, attached to the index of the cervix and upon which the uterus lies when antiverted the fundus resting upon the upper surface of the bladder.

The other ligaments of the uterus appear to be concerned only in the control of the fundus. The broad ligaments and the round hgaments can have no part in the support of the uterus. The latter with the uterus in anteversion are completely relaxed, the distance from their points of origin and insertion being considerably less than the length of the ligaments. The uterosacral ligaments are more difficult to be definite about. They are situated at a higher level than the pelvic fascia, and from the direction in which they run they would draw the cervix upward and backward. From their nature they do not seem capable of supporting the uterus, and a fact which rather bears this out is that in cases of prolapse they are found greatly elongated but not ruptured showing that they fail and stretch when the weight of the uterus is thrown upon them. There is no evidence that they are liable to damage in labor and therefore why should they so frequently fail in their function after labor?

Retroversion of the uterus is sometimes stated to be a predisposing cause of prolaps but there is clinical evidence that it is not necessarily the initial stage and from the mormous frequency of cases of retroversion in which there is no prolapse even when the rectoversion has existed for a very considerable length of time and particularly in those cases where it occurred after partuntion it may be concluded that the position of the uterus has no influence upon the supporting structures and that retroversion in the early stages of prolapse is only a concomiant and not a predisposing cause although it is an ultimate develor ment in all cases.

Although I have stated that damage to the levator an muscles has no effect upon the support of the uterus they and the faxan have a correlated function. The levator am form almost as complete a sheet as the faxen across the pelvis and these two sheets together form the pelvis diaphragm. The condition is exactly analogous to the abdominal walls

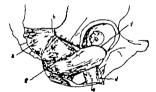

Fig. 4. Showing the invator and mousel from the cortains, it can be seen how impossible it would be for any inceration cartestizing from the weights to involve the posterior and certification of the control and certification can only involve the fifteen. Corceptens, it is child to be a surface to the control of the rection and the control of the rection and the control of the rection and the control of the con

where we have a containing sheet of fa_cia supported by muscles externally

Under normal circumstances and during ordinary movements of the body, there is a certain constant pressure varying between certain limits applied to the pelvic vi-cera This strain is altogether taken up by the fa_cia and although constantly applied has no detrimental effect upon its upporting power. Index abnormal circumstances the downward strain is increased and even though very far short of the maximum that the taskia is capable of sultaining the mulcles of the pelvic diaphragm come into action and temporarily support the ta-cia Thu it can be seen that the pelvic fascia is essential to the support of the pelvic viscera and without it prolapse mult occur. While the muscles are not exential but additional safeguard and in their absence it would be quite possible tor no prolapse ever to develop on the other hand the dependence upon the muscle is shown in thee caes of prelapse diveloins in old age in women who have never hill any cause for laceration or any tendency to prolapse during vigority life and in whim

In the majority of cases of prolapse there are found lacerations of the cervix which are not confined to the vaginal portion but ex-

tend out and involve the varinal fornices. If these are examined it will be found that they nearly always take a curved direction when they reach the fornices so that they partially encircle the cervix. They thus involve the attachment of the fascia to the for nices and cervix in a direction transverse to the fibers of the fascia. The degree of evident laceration is no guide to the extent to which the fascia is involved the fascia may be extensively lacerated even when the cervix is intact. The result is that the foscial aline across the pelves is interrupted the fascial ends being only connected to the viscers by loose connective tissue which stretches before the constant strain from above. The fascia is still there and the detached ends at their normal level, but the uterus is able to pass down between them.

Besides laccration in the region of the vaginal fornices laceration may occur in front of the cervix where the fascia bridges across the antenor forms and passes between the anterior vaginal wall and the bladder in which case the bladder protrudes between the edges of the fascia and forms a cystocele. These two varieties of laceration may exist separately or together When in the region of the lateral fornices alone, there results prolapse of the uterus with consequent inversion of the vaginal fornices, but there is no cystocele. The base of the bladder is still support ed and the anterior vaginal wall relatively long The prolapse is usually partial. When the anterior fascia alone is involved the uterus and vaginal fornices retain their nor mal position but the bladder prolapses form ing a cystocele displacing the free edges of the fascia outward and stretching the anterior vaginal wall. When laceration occurs in the two sites, there is prolapse of the cervix and vaginal fornices as well as a protrusion of the bladder the uterus comes down and the whole anterior varinal wall becomes inverted.

These different conditions should be clearly differentiated. They are all the result of laceration of the fascia, but the site of laceration is different. They are analogous to abdomland hernias through scars. The recognized method of curing these hermas is to clear the edges of the fascia and unite them directly and if this is done it does not matter how the other tissues are dealt with. Exactly the same condition prevails in the cases of prolapse of the uterus and cystocele except that the organs which become displaced have a definite position to which they should be returned, and are attached to the fascia whereas the contents of an abdominal hernia has only to be returned to the abdomen and the sac obherated

I believe almost all cases of prolapse and cystocele can be dealt with on these lines. There is no difficulty in reaching the fascia at the sides of the cervix and above the lattern formices, through an anterior colpotamy in cision when the bladder is pushed up from the front of the uterus and well out to the sides so as to clear the fascia above the lattern formices and by stirtiping the anterior wall away from the bladder at each side of the vertical function.

The old operation of anterior colporthaphy and colpoperineorrhaphy was most unsatisfactory but occanonally resulted in cures even in pronounced cases. I believe these cures were effected upon the lines suggested above. In taking away the anterior flap of vagnal mucous membrane the indision was made sufficiently far out to reach the pelvic fascia and enough was caught in the sutures to reconstruct the nelvice line.

In the present day operations for prolapse especially the Schauts Wertheim type there is one common feature the high amputation of the cervix which is done to reduce the size of the cervix and considered essential for success, although it must be admitted that numerous cases have very small atrophic uters and proportionally small cervical por times. The amputation is done well above the vaginal level and the stump covered by the vaginal flap.

I believe it is absolutely impossible to amputate the cervir as described, without reaching the pelvic fascin, and the curative results are due to the inclusion of the fascia with the vaginal mucous membrane in cover ing the cervical stump. As for the interposition part of the operation, it only relieves the cystocele and does so by using the uterus to bridge the gap in the pelvic fascia. It has no part in supporting the cervix and is incf fective in the absence of independent means for doing this It has the disadvantage that it necessitates future sterility and although this only effect, a small number of cases if they do not agree to it the only alternative is palled tive treitment or an operation which will only give relief for a hort time. A a result of failure with the Schiuta Wertheim operation there has recently been agreested a form of viginal by terectomy the author (6) of which say the interposition operation is very efficient in the relief of partial prolapse with exten ive ev toccle. The best results being obtained in cases under forty years of age it should not be adopted in the third and fourth degrees of prolanse. These cases are to be treated by hy terectomy, the broad ligament are to be united in the middle line and the free edges titched close to the urethr >vesical nunction so a to compel the bladder to rest on the broad he iment. In this operation the base of the broad ligament, when they are separated from the cervix are firmly united together and this I believe in the part of the operation which really cures the prolapse of the vaginal fornices and without which the elevation of the bladder would have no effect. It is again a reunion of the pelvic fascia which it done without removing the uterus would be really effective in curing the prolapse

What I wish to emphasize in connection with these operations is that the one common item is plastic work in the region of the lateral fornices and cervix but that the importance of this is not recognized and credit for what is effected by this is given to other parts of the operation which are not essential while many of the unsatisfactory results are due to non appreciation of what is the essential part of the operation in cases of prolapse

The lines upon which I suggest prolapse and cystocele should be treated were pointed out by Alexandroff ten or more years ago and advocated by Hastings Tweedy (7) but they have not been followed or recognized by the profession with the result that the surgical treatment remains unsatisfactory

and is chiefly upon lines which involve the interference with the tunetion of childbirth and 1 therefore rendered un intable for an important class of the -the younger women still in the childbearing period of lite and probably lesirou of having more children

THE TRANSPANCREATIC APPROACH TO THE COMMON BILE-DUCT

TRANSPANCREATIC CHOLEDOCHOTOMY

By ANTHONY IL HARRIGAN M D N w York Assetzet Vestis Server, Fording Benefits

THE operative measures available for the removal of calculi from the gallbladder and the upper part of the common bile-duct in a general way evince technical excellence and have welldefined indications for their employment. On the other hand, the underlying principles and the indications for the removal of gallstones impacted in the terminal part of the common bile-duct or the panilla of Veter are not clearly understood. This seeming obscurity as to the best method appropriate for the treatment of stone impacted in the terminal part of the common bile-duct is explained partly by the fact that owing to the infrequent performance of these operations the average surgeon has but a minimal experience in this field.

The methods proposed in the standard textbooks for the removal of stones in this region represent mainly the personal experience of individual surgeons. The deductions are not based on statistical analyses of large series of cases collected from many clanics. Any operation proposed for the removal of cakeuli impacted in the terminal part of the common bile-duct is necessarily intricate and difficult. Technical aimplicity is intrinsically impossible owing to the ana tomical relations of the structures concerned, for at this poant the duodenum, the pancreus and the common bile-duct meet at a common center

At the risk of being prolux, the writer adds another operation for the removal of calcult impacted in the terminal part of the common ble-duct. By this method calcult can be removed from the terminal part of the common bile-duct by an incison in the head of the pancreas. The operation may be proper by termed transpancreatic choledochotomy An experience occurring to the writer furnished the incentive to this study the object of which is to establish the practicability of

the operation he employed and to bring it forward into the light of publicity. In order to describe clearly the operation the topographical anatomy of the common bile-duct is briefly reviewed and an outline furnished of the operative methods usually recommended for the removal of calculi impacted in the terminal part of the common bile duct.

Anatomy of the common bile-duct Anatomists do not agree in regard to the terminology used in the description of the various segments of the common bile duct. The division appears artifacial and arbitrary The clinical surgeon has contributed an additional classification the terms of which express more or less a working knowledge of this region. A great deal of the confusion and obscurity of the terminology exist in regard to the terminal part. This is natural, as many anatomical textbooks fail to state clearly the exact relations of the common bile-duct to the pancreas.

The classification of Testut is generally used. He divides the common bile-duct into four parts namely the supraduodenal, the retroduodenal, the pancreatic and the intra parietal The use of the first two terms has been criticized by D Este on the ground of inaccuracy. He maintains that the common bile-duct is never superior to the first part of the duodenum and that therefore the term supraduodenal is a misnomer This is mentioned in passing but the soundness of the criticism is not considered as the main theme concerns the lower part of the duct. The common bile-duct measures 65 to 8 cm. in length. The supraduodenal part is almost a cm. long It is intimately related to the structures contained in the foramen of Winslow and to those leaving and en tering the transverse figure of the liver that is, the hepatic artery the portal vein, and the lymphatic vessels. At the level of

the toramen of Win-low the common duck occupies the tree border of the gar trobupation At the point the hepatic artery is but one to two millimeter, distant from the left border of the common bile duct. Oc ca ionally the artery divides prematurely remaining at hr t quite di tant from the com mon bile-duct ultimately (r) and the hepatic duct obliquely. the lower part of the pancreatic segment in conjunction with the intraparietal part by D'Este who states that the expression has a surgical value as it indicates the most fre quent site of calcul in this region. He insists that these two sections should be combined and considered as an anatomical entity

OPERATIVE METHODS EMPLOYED FOR THE REMOVAL OF IMPACTED STONES IN THE COMMON BILE DUCT

In general, an endeavor is made to push the stone into the supraduodenal part where it may be removed through a small vertical incision If the stone is adherent, usually to the mucous membrane a pair of forcers may be introduced to free it. Irrivation is of doubtful value, though it may ald in the removal of small stones. Massage or manipula tion is better but one must be careful not to crush the stone as the small fragments may remain as nuclei for secondary calculi. operation, called choledochotripsy was first done by Courvolater It is indicated in soft cholesterin stones. A major objection is the possible persistence of the detritus to form nuclei of secondary calculi.

When manipulation, irrigation, and massage fail, which is sedom, a direct attack is imperative. The question now arises as to which anatomical approach is best.

The exposure of the common bile-duct where it lies behind the duodenum, by mobihration of the duodenum as suggested by Kocher is of great utility and has many advantages. The technique employed to ac complish this operation has been formulated clearly by Kocher who emphasizes the ana tomical importance of the posterior parietal peritoneum which passes from the duodenum to the anterior face of the kidney forming ultimately the upper layer of the transverse mesocolon In freeing the duodenum the duct is carned with it. It is plainly exposed, and may be directly palpated. When the duct is incised the operation is called retroduodenal choledochotomy It is doubtful whether direct incision is of value. In emaciated patients, the continuous loss of so much bile to the body through external drain

age is objectionable. This opinion is held by Kocher and Lennarder who believe that in these cases the bile should be left, if possible to drain into the intestine. Again, injury to the duct of Wirsung is possible, as has occurred at the hands of Kocher and Kraske. Berg afters the technique by draining the hepatic duct. The incision in the common duct may then be sutured. The possibility of retroperational suppuration is an additional argument against incision into the duct in this region.

The chief value of the operation of mobilization of the duodenum is that the stone may be dislodged and pushed up into the supraduodenal part where removal is easily effected. Riedel, Payr Lorenz and Berg state that the stone can be displaced in the majority of the casea. However Kocher and Kehr agree that this is occasionally impossible owings to the existence of a pericholedochitis or to the encirclement of the common bile-duct by pancreatic tissue.

The transduodenal operation was first performed by McBurnev and soon repeated by Czerny and Mavo Robson Kocher states that this is the best operation for an impacted stone in the ampulla. He recommends mobilization as an aid in the operation. The duodenum should be opened transversely as there is less likelihood of wounding the blood vessels and the resulting wound is easier to suture. The papilla may be cut, though often simple tearing or expressing is sufficient. The duodenum is sutured in the usual fashion.

That another operative method cruits for the removal of impacted calculi in the ampulla of Vater is not widely known. This route is through the head of the pancreas. The writer has performed this in one instance where the pathologic and anatomic conditions prevented the use of other measures. The choice of this method was entirely fortuitous, as he was unaware at the time of any previous work on the subject. Although hinted to a ungle case, his personal expenence demonstrates that it is feasible to remove calculi from the ampulla of Vater by direct attack through the head of the pancreas. The patient presented every complication tending patient presented every complication tending

to make difficult any abdominal operative procedure that is a large fatty pendulous abdomen extreme distention of the intestines and a marked depth to the wound. The brief survival of the patient naturally eliminates from the di cu ion in the par ticular instance, the possibility of objection able sequelæ as pancreatic and duodenal inflammation or h tula. It i indeed regret table that the clinical test is lacking. H w ever the pathologic investigation obtained is of value in showing the absence of any injury to the duct of Wir ung

To illustrate the operation the following case is reported. The patient was admitted to the econd surgical division of Fordham Hospital in the service of Dr W P Healy through whose courtesy the writer operated on and reported this case

and the abdomen be ame markedly distended The patt nt vas so rewhat tupe rous and apparent ly extremely t ic. The face was somewhat y anotic. The tongue vi pated. The heart sounds were distant though no murmurs vere heard Examination of the lungs was negiti abdomen as tremen lously distended. The abdomin I wall was ry thick with fat. Ther was slight rigidity and t aderness in the upper right qualrant The abdomen was tympanitic through out Temperature 102 3 5 Julse 130 respira tion 30 Leucocytosis 23 000 83 per cent poly mort bonuclears

The lesion was recognized as existing in the upper abdomen. Acute pancreatitis was decided upon as the most likely diagnosis owing to the existence of the extreme distention coupled with the peculiar evanotic appearance of the fa e These two symptoms we have noted occurring fairly oft n in a ute pancreatitis Immediate operation was decided upon

Operation Lither narcosis The intestines were tremendously distended. A systematic exploration showed that the liver was enlarged but no abscess was present. There was a moderate amount of brownish fluid in the right flank. The omentum presented a chewed up appearance character istic of fat necrosis. The pan reas was greatly swollen and enlarged The gall bladder was tense It was opened and five stones were removed from the cystic duct | lalpation through the duodenum disclosed a calculus situated in the terminal part of the common bile-duct. All efforts to displace it up into the supraduodenal part failed. Owing to the obesity mobilization of the duodenum was im

possible No effort to incise the posterior penton um uld be made with success or saf ty Also the depth from the margin of the vound to the du denum was so great and the distention so marked that I desisted from opening it. As I held the duodenum forward on my tinger. I indirectly litted up the pancreas. The idea came to reach the ston through the pancreas. A small nik was mal in the pan reas and I qui ally came up in the ston. I in ised the fuct vall and we about to grit the stone when the ut perting hand ever ming un lue pre-sur cau-ed it to slip un ler the duodenum t the lift. However two more stines lying immediately above as peared in the wound and were casily removed. The e had undoubtedly been lying al ye the ripa (of ton

of exit tithe drains

Following the operation the rules increased in frequenty and became exceedingly feeble despite vigorous stimulation. Death occurred twelve hours after cheration.

A partial autopsy was permitted at which the duodenum and jun ras were removed in toto The specimen was runin d by Dr Charles V (arsid pathelogit to Fordh in Hospital who re part as follows

D s ription / g ss specimen The specimen con sists of the head of the pancreas to which the second part of the duodenum is attached. A the duode num was opened the papilla appeared to be very much enlarged and the tissues around it infiltrated and necrotic

The common life-duct presents behind the pan creas. It is greatly distended being o mm in diameter 1 probe passed through this emerges without difficulty into the duodenum. The duct

of Wirsung appears to be patent

The pancreas itself is of large size and firm with an occasional area of hæmorrhage Section was taken of the papilla and of the hemorrham areas and non hemorrhagic areas of the nancreas Mi oscopical tindings The duodenal mucosa is

The epithelium of Brunner's glands is necroti largely desquamated. The puritoneum is richly intiltrated with polymorthoniclear leucocytes The surrounding lymph nodes are inhitrated with polymorph nuclear leucocytes The common duct shows only redema f its walls and desquamation of its lining cells. In the pancreas one ands first a ten areas of cystic dilatation of du is and acini each the seat of a very a tive desquamation cross section of one duct presents an occluding mass of highly refractile bile-stained material othe ducts are crowded with neurotic cells polymorphonuclear leu ocytes and bacterial olonies

There are wide areas of pancreatic tissue in which all semi lance of actnar transcement is obscured, hasy consisting of masses I actuar cells in all stages of degeneration in these areas there is no linfliration. In still other areas there are cir cumscribed food of polymorphomiclear inflintuiton which have not as yet undergone liquefaction necroals. In some of these food barterial colonies appear. There are a few areas of fat necrostary of the section presents evidence of moderate fibroris.

Dispassis Suppressive penersatitis, probably following a catarrhal inflammation, because of obstruction of ducts, the bacterial invasion coming from the d odenum via the duct. Such an occurrence is readered probable by the finding of bil stained material within the small ducts of the puncreas.

Conclusion This operation demonstrated that it is feasible to remove calculi from the ampulla of Vater by direct attack through the head of the pancreas. An investigation of the literature was undertaken to discover if this particular operation had ever been performed before. It was found that the operation had been performed by Tansini, Terrier and MacGraw in order mentioned chronologically making a total of 3 cases. In all these the operation was employed as a method necessitated by the peculiar anatomic or pathologic conditions existing at the time The three cases are detailed here for the sake of completeness. Kehr states that Keen successfully reached and extracted calcula through the head of the pancreas. A search of the literature fails to find this reference

ported by D Este The patient Stef no s case was a woman presenting the classical symptoms of stone in the common duct. An oblique incusion was made, parallel t the right costal border \ery dense adhesions existed between the hepatic flexure, the great omentum, the superior angle of the duode num, and the margin of the liver The exploratio proved difficult. After separating the adhesions at the edge of the liver the gall-bladder was isolated and a calculus removed. Catheterization of the and a calculus semoveu. Califererization of the biliary duct was impossible. No guide or probe could be passed. The gall bladder was removed. An effort was made there the common bile-duct at the level of the foramen of Winslow The re porter states that Stefan discussed with the stu dents present in the amphitheater the advisability of retroducdenal exposure of the bile-duct, but ultimately decided that it was impossible of e ecu tion. The reason is not stated but probably the dhesions prevented. On the same ground most likely he did not employ a dvodenotomy. In the angle between the superior mesenteric vein, the head

Grasping the pancress with forceps and lifting it up he discovered that the pancreas presented the signs of chronic inflammation with scierotic changes. An incision was mad over this mass. The common bile duct was isolated. It was dilated and at th point of entrance into the duodenum was a swelling w thin the lumen An incusion was mad into the common bile-duct at the sit of the calculus, which incision involved slightly the outer cost of the duode num. The inferio pole of the calculus lay i the intrap netal portion f the common bile-duct Sutures ere introduced before the removal of the ston which was firmly adherent to th wall the d ct Some turbid bil followed the removal of the stone Retrograde catheterization falled t disclose the existence f additional calculi. Lembert sutures were pphed t that portion f th deodenum involved in the incision. Double drain age was instituted. One tube was placed in the cystic d ct a second in the common ble-duct and the third passed dow to the beld of operation. The wound was then dosed. The drainage was excellent. The cystic duct fistula closed rapidly The common bil d ct tistula took a long whil to heal, though ultimately complete closure occurred The patient mad complet recovery

Terrier's are Biliary lithians cirrhosis holedochotomy death. The patie t was man 32 years of age Vertical incino about ten inches along margin of abdominal rectus, on right side exposure of peritoneum. The transverse which was adherent t the lower surf ce of the liver was detached and turned down but the gall-bladder could not be found. Imbedded in th. head of the pancreas, a stone co ld be distinctly felt evidently in the choledochus Unsuccessful ttempts were made t crush this calculus and t push it toward the intestine. Placing the fingers of the left hand a little behind and below the head of the pancreas, th operat cut d wa directly upon the culculus and opened the choledochus. The stone was then removed it as roughened f oval shape 114 inches long and nch wide C theterization of

of the pancreas, and the duodenum, the operator

felt an abnormal resist nce, deeply astuated.

contained a little blood stanced fluid.

**MacG ors case: The petient was a w man, 36 years old. The chief complaint was J undice I nive months duration, associated with abdomination. A right rectus includes aboved an enlarged liver. There were no stones in the guil-bladder cystic or common ducts. A large hard t mor was

the choledoch served t abow the permeability f the canal above and below the incasi which had

been applied for the withdrawal of the calculus. Suture of duct large drainage tube under the lower

surface of the liver near th hilus Operation lasted

about one hour and a half. Death on second dy following the operati. Autopsy sho ed that the incised ampulla. f \ ter was completely closed by the surures. The drui, which extended from

the pancreatic incision t the abdominal wound

felt in the head of the pancreas. The pancreas was incised carefully and deliberately the common bile-duct was exposed opened and the gall stones easily expressed. The pancreas substance at the side of the incision was 1,6 inch in thicknes and relatively vascular. There was only a moderate flow of bile. The stone vas round and measured 2 inches in circumference. The pancreati wound and the common bile-duct wire sutured with lan garoo tendon. A rubber drainage tube was in serted and the wound was partially closed. Recovery.

In order to determine the usefulne and practicability of this tran panere, the approach to the common bile duet the author reproduced the operation in the anatomical laboratory of Fordham University Medical School

In a male cadaver the upraduodenal part of the common bile-duct was incised and two leaden shots introduced and pushed down to the end of the common duct in order to simulate the operative findings. The quadplateral described by Quénu was easily recognized. The second and third tinger of the lett hand were placed behind the second part of the duodenum while in front the thumb of the left hand acted as the palpating finger The shot could be easily felt. By flexion of the second and third fingers and an upward pull the entire anatomic lying upon these two ingers was lifted up and brought forward. This rendered the pancreas quite accessible. The pseudo cal cult were again palpated and with the pan creas parenchyma lying over them were brought forward A pair of blunt pointed scissors tore through or dilacerated the pancreas and exposed the terminal part of the common bile-duct immediately before its junction with the duct of Wirsung The common bile-duct was then nicked longitu dinally and the shot exposed. They were easily expressed The common bile-duct was recognized by the dark color it presented in contradistinction to the white pancreatic tissue. The technique proved simple and this particular cadaver demonstrated the feasibility of removing a leaden shot from the terminal part of the common duct by incising its wall through a preliminary incision in the head of the pancreas without injuring the duct of Wirsung Following the

operation the duodenum and pancreas and the common bile-duct were removed in toto A careful dissection subsequently showed that the duct of Wirsung was patent intact and uninjured

The exeutrence of injury to the canal of Wirsung during pancreatic operations cau ing troublesome it tula is probably extremely exaggerated La Courtre and Charbonnel collected sixteen cases of pancreatic lithia i which had been subjected to operation There were three immediate death foll wing exploratory incl ion and two deaths acurring within a few days. Allen's patient died at the end of the fifth day Two pancreatic calcult were removed from a pancreatic cv t situated between the liver and the st mach In Pearce Gould's ase death occurred on the cleventh day. A stone had been removed from the canal of Wirsung Autopsy sh wed multiple calculi in the pancreas a sociated with a hydright cyst of the liver. In the remaining cases subjected to operation which recovered no mention whatsoever 1 made of the occurrence of pancreatic is tula

In passing it may be mentioned that Cherecelli has performed experimental suture of the duct of Wir ung. It is a teasible operation. However from a study of the above cases of pancreatic lithiasis there is slight occasion for fear of the development of troublesome complications if the duct be accidentally divided. As to the possibility of injury to the duct of Santorini very little is known.

The lesser duct lies as a rule on a plane central to the main duct. As to the result of its division the writer is unacquainted with any clinical or experimental reports which would throw light upon the question. It is extremely probable that its division accidental or deliberate would be negligible.

The anatomical researches of Baldwin afford valuable information in this respect. He found that in 13 a per cent of the cadavers (to out of 76 specimens) the a cessory duct failed to join the main duct in 86 8 per cent of the cases (the remaining 66 specimens) junction was effected with the main duct in the head of the gland close to the neck. We see therefore that in 86 6 per cent of the

cases the accessory duct has two termina tions. It seems natural to conclude that the division of its duct in any part of its course would not lead to either obstruction or leak are of the pancrentic secretion. The occurrence of hamorrhage might be claimed as an objection to the employment of the transpancreatic route. In the cases of pancreatic calculi, this objection does not exist, for it has been shown by LaCoutre and Czerny that pancreatic stones tend to exteriorize themselves and push back the pancreatic tissue so that the covering layer becomes quite thick and relatively anamic. It is possible that this process takes place in the case of biliary calculi. The investigations of Ouenu mentioned above, as to the relative thickness of the pancreatic tissue situated in front of the common bile-duct should be kept in mind. This pancreatic crust is so thin that it would appear that no extreme amount of pressure is needed to make it relatively anamic. Moreover the writer's personal operative experience did not demonstrate the occurrence of hemorrhage, and the cases of Tansini, Terrier and MacGraw do not lend any amport to those who would object to this operation on the ground of troublesome hemorthage.

It should be recalled that an inclaion of the pancreas in the particular region has been warmly recommended by Vautrin for the treatment of chromic pancreatitis. He advocates the division of the collar of pancreatic tissue which compresses the common indiculate. This operation has been employed by Vautrin, Martino and Leerny No men tion is made by Vautrin of these surgeons meeting hermorrhage in performing this type of pancreatotomy

These three objections, injury to the duct of Wirsung pancrestic fistula, and the occurrence of severe hemorrhage seem to lose in strength when the anatomy of the pancreas and the clinical reports of pancreatic operations are carciully studied. That these objections are real, no one can doubt. That they are valid, is open to question. Never theless, these objections are sufficiently real and strong to prevent the selection of the transpancreatic route for impacted calcul,

when the retroduodenal or transduodenal routes are available. However if these routes are impracticable owing to complications, such as occurred in the writers case and in the cases of Terrier Tansin, and MacGraw where the adhesions were extensive the operation of transpanceratic choledochotomy has a definite field of usefulnes.

ominic near or userniness. The advice of a surgeon in regard to a technical procedure naturally rests ultimately upon the great familiantly of the surgeon with that particular operation. Many operations can be based on d priors anatomical technical and physological grounds, and the real test is a definite practical experience on the living For example the extreme intestinal distention of acute pancreatitis may render a certain operation impossible or on the other hand, in a thin wasted, and emaciated patient, with collapsed intestines, the technical difficulties are dimmished.

If one were certain of the calculus being lodged in the lower portion of the pancreatic part of the common bille duct, an incision directly backward into the pancreas mights be indicated. If the calculus were partly in the intraperietal part of the common billeduct, the stone could be reached by an oblique route through the head of the pancreas, approaching the upper part of the calculus so as to come upon it from above downward thereby guarding against injury to the duct of Wirsung.

It may be difficult to determine whether a fund of the calculus rests in the common duct or whether it has completely within the wall of the duodenum. The danger of leakage from the intestine seems remote so long as the papilla is intact. The opening through which the stone is removed is exceedingly small

The operation of transpanceratic choledochotomy is presented for consideration as a measure of occasional applicability and usefulness. The writer has no intention to urge or even to suggest that this operation be used to suppliant the older procedures now in vogue.

EXCISION VERSUS CASTRO-ENTEROSTOMY 1

By VAN BUREN KNOTT M.D. St. City Town

URGIONS of experience have long since recognized the value of gastroenter istomy in the treatment of gastric and duoden il ulcer. When the indications for its performance are present and when done by competent hands the results following this operation have justified the confidence with which it has been so frequently employed. It must be admitted however that like many other surgical procedures which have been popularized by competent men it has been too frequently employed when sufficient indications for such employment did not exist.

It is a well established fact that a gastroenterostomy made in the absence of well defined and understood pathological conditions involving the stomach or duodenum or both will prove worse than disappointing Let far too many operations are being per formed by surgeons who open the abdomen expecting to find an ulcer and who tailing to find one can think of nothing clse to do than the gastro-enterostomy which they had decided one or two days before was the procedure necessary in that particular in stance. The value of any surgical procedure cannot be determined by men not qualined or by the recital of experiences in which such procedure is clearly contra indicated

Therefore we may assume that it has been the abuse of gastro-enterostomy rather than its proper and rational application which has brought it more or less into disfavor

It is with full appreciation of the value of gastro-enterestomy when properly employed that I protest against its employment in every case of ulcer treated surrically

Statistics now available from many large clinics prove most conclusively that in approx

imately 70 per cent of patients afflicted with ancer of the stomach it is implanted upon an old ulcer hase. It is recognized that the tassue changes which accompany chronic gastric or duodenal ulcer are more or less permanent and potentially cancerous Rod man recognizing this years ugo recommended that where the pylonic region was the seat of an ulcer or ulcers which presented much thickening or other evidences of malignancy a pylorectomy be performed and this principle for ulters so located has been more or less generally recognized and employed

It would appear however from a perusal of literature pertaining to gastric surgery and from impressions gained in attendance at various clinics that ulcers situated in other regions of the stomach than the pylorus are not excised as frequently as they should be With the tendency to cancer development upon an ulcer base regardless of its location in the stomach wall the duty of the surgeon toward these patients is clear

Ulcers so situated as to permit excision without particularly increasing the immediate risk of the operation should be excised Moynihan (1) states that in reviewing his early work when gastro-enterostomy alone was employed in the surgical treatment of ulcer about one third of the number of patients only could be pronounced 'cured Another third after a varying period of freedom from symptoms had to submit to a second operation in which a pylorectomy or excision of the ulcer was rendered necessary after which they experienced lasting relief The remaining third developed carcinoma of the stomach from two to five years later

His experience which parallels that of many other surgeons furnishes additional reason for the more radical treatment of ulcer at the primary operation. The fact that one third of the number of patients with gastric ulcer who have been treated by gastroenterostomy alone by a master of gastric surgery require a second operation for the removal of the ulcer before obtaining complete relief from distressing symptoms, should command our tamest attention.

Because of the rich blood supply and thickness of the stomach walls, the repetr of a wound therein is rendered not only extremely easy of accomplainment, but practically certain as to prompt and firm union. Ulcers situated upon the anterior surface of the stomach and not involving the curvatures may be very readily excised and should in practically every instance be so treated.

Ulcers located in the pylone region upon the anterior wall may as a rule be readily seriesed and should such excision result in narrowing of the pylorus a gastro-enterostomy should also be made. If several ulcers are present in this region or if the thickening and induration attending one ulcer are extreme a pylorectomy or Rodman operation should be done. Pylorectomy is a somewhat more formidable procedure than simple excusion or exclaion and gastro-enterostomy and should be reserved for those cases where pyloric involvement is general and extensive.

Ulcers involving the leaser curvature may be excised by the method of Moynihan (2) followed by gastro-enterostomy which he states should always be done in such cases following excision because of the resulting stomach deformity. It is surprising what results may be secured by this method in ulcers involving so much tissue on either aide of the curvature as would appear at first sight to render their complete removal out of the question. However many ulcers so situated will be encountered whose complete excision is out of the question because of adbesions and extensive involvement of the stomach wall, and in such instances we are forced to be content with gastro-enterostomy

Ulcers upon the posterior wall of the stomach may be excised if not too adherent,

either by employing the rotation method of Summers (3) or the transgastric method advocated by Chaput (4) Deaver (5) and others. I have employed both of these procedures with much satisfaction and have been surprised and gratified with the case of their performance in suitable cases. Because of adhesion or maccessibility not all ulcers of the posterior wall can be excised and a gastro enterostomy must suffice.

Ulcers high in the cardiac end of the stom ach are not amenable to excision nor are they benefited by gastro-enterostom. Jejunos tomy offers the best prospect for relief to patients so afflicted.

When operating for perforation of a gastne or duodenal ulcer excision of the tissue involved in the ulcerative process should be done whenever possible before attempting to close the rent in the stomach wall. This removal of diseased tissue not only facilitates immediate wound repair but also lessons the tendency to recurrence.

Whenever possible after excision of an ulter or ulcers the suture line should be re inforced by an omental graft or flap as long ago recommended by Senn, as thereby the danger of leakage is reduced to the minimum.

As experience increases it will be found that more and more uker bearing tissue may be treated radically by excision even to the point of making when necessary a partial gastrectomy for ukers so situated as to require the same for their removal.

Gastro-enterostomy may frequently be necessary as a supplementary procedure to excision of ulcers wherever situated and should in such instances never be neglected Belleving that the ulcer of today is the cancer of tomorrow it is urged that in every suitable case the ulcer bearing tissue be removed by whatever means or method is in that particular instance most safe and practical.

THE ADVANTAGE OF SEPARATE SUTURE OF THE MUCOUS MEMBRANE IN CASTRIC SURGERY:

BY RICHARD A BARR M.D. FAC. NAMELLE TE AF 1E

If he untortunately been proved to the sate faction of mot observer that imple gistrojejuno, tomy with it low mortality of 1/5, to per cent will be definitely curative in less than half the cases of chronic hart two third of the cases of chronic duodenal ulcer that come to operation.

That many ulcers do not yield to medical treatment, and yet are permanently and completely cured by urgery (umple or complicated) is a fact a firmly established as that ga troje unostom is not a cure all. More than this that properly applied surgery can cure every existing ulcer of this region is a reasonable expectation, though the cure may

be effected at a great risk

Leaving out all consideration of cancer actual or notential the cure of ulcer by urgers can only be positively assured by resection or permanent exclusion of the involved area Drainage and the admission of alkaline ecretions into the stomach may give temporary relicf of symptom. The much may be and often is accomplished by ga tro-An opening at the usual ite iciunostomy of the posterior gastrojejuno tomy dies under some condition. (pylorospa in for instance or in case of very large stoma; hasten the empty ing of the stomach and does admit the bile and pancreatic juice into the stomach Animal experiment. A ray observations and average climical results all go to prove however that to act advantageously a moderate sized artificial opening mu t be assisted by spasmodic or organic closure of the pylorus. Nature ignores to a greater or less extent the artificial opening unless obtruction exist at the natural one. This is an established fact and many ills besides recrudesence of ulceration result from the presence and disuse of the new opening

My own idea of the proper way to view a gastrojejunostomy is merely as a new channel for food. This new channel is neces itated by reason of the feet that a atriagit in or operation) has caused (1) use of the pvi ru. In other word, it bear somewhat the sim relation to the urgery of ulcer (1) the tomach and du identime that (3) at my disc, it the urgery of capital by the restum.

To exert we result curative influence on in ulcer of the tomach or duodenum urgers must either new the ulcer or exclude the area occupied by it not only from the passige of lood but even it misonitat with the acid of lood but even it misonitat with the acid.

La tric secretion

Thee object can be accomplished in du xlenal ulcer by clo ure of the fixloru pyleric ulcer by pylorectomy or closure on the preximal ide in all other by re-ection of more or less of the tomach including the pyloru in suitable cases. Where the resection does not include the pyloru at might be wise at least to occlude it for or phylactic purpose. The reasonablenes of the would be more a ured if we knew the etiology of uker more definitely. However prompt emptying of the tomach and the admit ion of alkaline secretion are doubtles, beneficial experimental ulcer cannot be produced in the absence of acidity) and these an be assured by gastroleiunostomy when done a adjunct to pyloric closure

This tatement of the case sounds extreme and yet it we are to do anything definite for non perforating and non tenoring ulcer thi. is almost the irreducible minimum Fortunately most ulcers are so ituated that do ure at or near the pylorus will meet the indiction. When pylorectomy or resection elsewhere is required the surgical rik will not be out of proportion to that it that

pathology

In doing the limited work I have had in tomach urgery I have been torn between the conviction that only radical mer urewould get result, and the lear of the mort diffy associated with these radical measures.

The technical difficulties of resection of the

ith narros mi bandle or similar instrument.

these difficulties to an appreciable degree. This technique has been used to a greater or less extent by others but I do not believe its advantages have been duly appreciated. This use of the mucous membrane is most satisfactory in occluding the pylorus. For this purpose an incision is made on the anterior surface of the stomach, or of the duodenum according to conditions. incision is carried down to the submucosa

which in all succeeding description will be

included in the term mucous membrane. The

incision should be preferably transverse to

it should be done. By solitting the stomach

wall so to speak, and using the mucous and

submucous coats as one layer and the serous

and muscular coats as another I have avoided

the long axis of the organ and should extend from border to border

When the mucous membrane is reached the overlying tissues are removed from its anterior surface for at least an inch, and for as much more as may be desirable posterior surface is freed by blunt dissection with a narrow knife handle or some similar

The mucous membrane is der of mucous membrane (Fig. 2) The clamp is then removed and the mucous membrane divided along the groove left by the clamp

When the length of the cylinder of mucous membrane permits double clamping with in cision between the clamps, this should be done as it simplifies suture or ligation of the stump When double clamping is done. I always prefer suture to ligation and us. linenwhich is put in with two needles just under the clamp after the fashion of a harness stitch (Fig 3)

As the next step of the operation a rurse string of catgut or linen is thrown around the base of each stump (Fig 4) This purse string is put in the angle of tissue where the exposed mucous membrane terminates, and it may be placed in the mucous membrane itself but preferably should be in the muscular The stumps are inverted and the purse string tightened. When the width of the stomach makes a purse string undesirable as may readily happen on the proximal side a continued suture approximating the ante rior and posterior walls in the inner surface of the overlying muscular coat will serve the

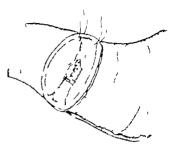

Fig. 3. Shaving method fluturing half i polition distribution of the plane of multiple at multiple in the plane of the pla

same purpose. The seromuscular tiscues are then closed the edges of the wound being inverted so as to bring the peritoneum in contact with the muscle of the posterior wall or the edges of the seromuscular wound may be brought together by utures which also eatch the posterior wall.

Instead of inverting long tump of mucous membrane the stumps may be ligated (or preferably sutured) close to their bases and then cut short. The makes the inversion less attended from the location of the ulcer the dissection has to be carried across the face of the ulcer leaving possibly an opening in the membrane corresponding to it. Inversion of the stump gives an additional sense of security and yet is probably not of any special value provided the mucous membrane is tummed short.

When the ulcer is of suitable size and located on the anterior wall it may be surrounded by crescentic incisions running from curvature to curvature down to but not through the microis membrane and the dissection and ligation of this structure completed a. jut tidescribed (Fig. 5)

It would appear at first planet that an incision in the long axis mid vas between the border would be most satisfactors, but there are several objects ins to the. First, the ulcer would be more difficult to avoid or to include by encirching. Then the closest attachment of the overlying structures to the much unambrane is found at the borders and here we get the most harmorrhage in separating them. At the extremities of the tran verse met ion, whave immediate areas to these.

lik 4 kjædnig det flat eln throne und the best him

border and also to the policitor urface of the maccal membrane

In doing this little operation it will not usually be necessary to ligate the omenta at the upper and lower borders of the vicus but this can be done if hamorrhage is at all troublesome

The advantage this method of occlusion had over the Biondi method and variou other methods with or without dissection of the mucous membrane is that it is more apt to be permanent, and is equally as simple as an except the ligature methods which are least reliable.

The advantage of the procedure over von I isolberg's exclusion it that the omenta do not have to be divided and the pylorus does not have to be mobilized. I further than this the cavity of the viscus is not opened up ind the inner surface of the mucous membrane i not exposed to the same extent. Closing a seromizeful ir wound on the anterior urface of the stomach or duodenum is a very much less difficult job than closing the two spening lett by day in on of all tile.

There is mall choice in technical difficulty between unflateral exclusion and Radman pylorectomy and between these two procedures I would choose pylorect my. The only idvantage the procedure just described has over pylorectomy is that it is made and performed, and it serves almost the same

Fig. 5. Method of rescribing an ulcer of suitable size on the anterior wall,

Should the location and extent of the ulcer at or near the pylorus or the presence of adhesions prevent the use of this technique and yet cicatrization should not have produced an efficient and permanent stenous, pylorectomy at some later date primary or secondary to the gastrojejunostomy is of course indicated.

In doing pylorectoriv the mucous membrane can be handled in much the same way as just described. After the oments have been tired and you are ready to divide the viscus, with or without clamping the diodenal end of the area to be resected, cut down upon the mucous membrane anteriority and posteriority and dissect up a short area of it as already described for pyloric occlusion. Double clamp this mucous membrane cut between the clamps, suture or ligate the distance of [7] of and then suture the seromuscular structures over this stump inverting the serom cout carefully.

The incision through the stomach at the opposite end of the resected area is handled in the same way (Fig. 6). The mucous membrane is closed by the harness stitch of linen already mentioned which is drawn soug as it

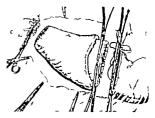

Fig 6 Showing technique used in pylorectomy

is placed (Fig. 3). The muoous membrane may be satured close up to its line of reflection from the muscle and cut short, but the overlying structures are more easily and smoothly closed if the mucous membrane is long enough for its sature line not to hold the anterior and posterior stomach walls too rigidly in contact

I have found this method of closure tech incally much easier than the ordinary one, and that the line of closure is much smoother and less bulk. Harmorrhage can be accurately and permanently disposed of as you proceed Rubber-covered clamps may be used for the temporary control of hemorrhage and being used for this purpose alone may be loosened at any time for the detection and control of vessels that would bleed.

In performing gastrojejunostomy I use no clamps except a small Murphy clamp at either end of the proposed incision in the jejunum. It is at times difficult to get room on the stomach for a gastro-enterosom clamp and once applied the clamps necessi tate a blind method of controlling hæmor rhare.

In the absence of clamps the viscers are held in contact and supported outside the abdominal wound by sutures which catch a good bate on each organ just beyond the limits of the proposed lines of incision. The incusons are made down to the mucous mem brane, and this structure cleared for a space half an inch wide at the center of each in

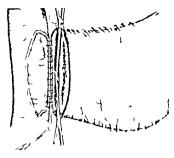

Fig. Ca to all tomath hold liked by clamps mucou membrane until post non-seromuscul risuture lin is completed in gastrojejunostom;

cision and tapering to the angles posterior cut edges of the scromuscular layer are united by a continued uture, the mucous membranes are then increed down the center of the exposed areas, the cut edges are united all the way round with a whip-over uture and the seromuscular suture completed ante-Cateut is used throughout rt irly inner layer of sutures placed in thi, way is a more ample procedure to accomplish than the usual through and through suture the uture line when complete i. more flexible and more readily pu hed out of the way for the seromuscular uture to follow 1 third line of sutures may be used if desired

If in doing a primary pylorectomy it is considered desirable to anastomisk the cut edge of the stomach into the jejunum after the method of I olya, the resection of the tomach is carried out as already described. The union between the stomach and jejunum is made as in ordinary gastrojejunostomy (Figs. 7 and 8) except that the cavity of the stomach is kept closed by the clamps on the mucous membrane until the posterior sero muscular suture line is completed (Fig. 7) and when these are rumoved by rubber-covered clamps as ordinarly used.

In the Journal of the American Medical Association of September 25, 1915 Dr W J

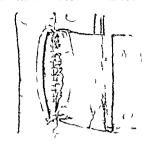

Fig & I out rk sermine ull uture life smillt l and rubber speal lamps in pla

Mayo described a method of excision a ulcer of the body of the tomach accessible from the scroul urface and not exten in economic to demand more rudical measure. A seromusular flip is raised the ulcer interized the opening closed by a turres placed in the muco ubmucou, coat and the flap replaced with overlipping. Dr. Mayo advises gastrojejunostomy but say that blocking the pylorus has not seemed to have added any thing to the operation. He get results with out blocking, but many of us cannot

I have been experimenting on dogs with a wire snare for dividing the nucou membrane in gastrogeimostomy after the inner line of sutures has been completed both posteriorly and anteriorly except for the mall space required by the snare. The snart has worked yer well so far as results in dog are concerned but such a struin is thrown upon the sutures when the tissues are drawn upon during the crushing action of the snare that have not tried it upon a human subject.

I will say in conclusion that unless you have given the matter special attention you probably have no idea what a trugh abstantial structure the nucous and submucou coats of the stomach make. The perstoneum and muscle are much more readily divided it is easy to cut down to the submucosa and leave it intact and the overlying structures are readily detached from it.

MELANO-EPITHULIOMA

A REPORT OF SEVENIA CABES

B ALBERT COMPTON BRODERS M.D. AND WILLIAM CAPPENTER MACCARTY M.D.
ROGHERTER, MANAGEMENT
Lord the Mice Clause

THE variety of symonyms which have been applied to pigmented malignant neoplasmata indicates a lack of uni formity of opinion as to just what these tumors are histogenetically have been described as melanosarcomata melanocarrinomata melanoblastomoto melanomata. melano-epitheliomata melanotic sarcomata, and chromato-The majority of writers utilize phoromata the term melanosarcoma which has its basis of usage in the old classifications of neoplasmata These classifications were founded upon a theoretical conception of the specific origin of tusties in the three embryonic layers The principal cells of nævi or moles having been thought to have their origin in connective tissue of the akin were therefore mesoblastic and hence their neoplastic deriva tives have been called sarcomata

The conception that the spindle and oval cells which are characteristic of melanotic neoplasmata of the skin are of connective tissue ongin is founded upon morphology which we are rapidly learning is not an accurate criterion for the embryologic origin in any special embryonic layer. Morever the direct continuity of the spindle and oval cells with the basal cells of the skin can be readily demonstrated not only in new! (Fig. 1) but also in melanotic neoplasmata (Figs. 2 5 4 and 5)

The cells of the latter condition frequently assume an alveolar arrangement (Figs. 6 7 and 8) which 1 very characteristic of opithelial tumors Such alveolar growths have been called alveolar sarcomata and en dotheliomata the latter term inferring their origin in the lining of vessels. In the authors experience no evidence of vascular structure in connection with the alveolar arrangement has been demonstrable. (Fig. 8)

We desire to utilize the term melanoepithelioma for the following reasons

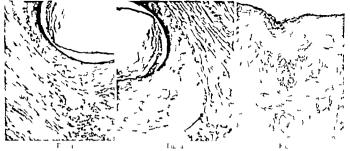

If the ld three layer hypothesis for the classification of timors be adhered to it may be well to remember that the pigment bearing cells of the skin (Fig. 9) and perhaps the chroid (Fig. 10) both of which familish the source of all of the timors of this series, have

Fig. (a₀ 6) A section of mole showing the direct connection between the stratum germinativum and the subenithelial cells hich are characteristic of moles

^

their origin in the ectoblistic layer rither than the mesoblastic layer. There still seems to be however some doubt as to the exict origin of the pigmented cell of the choroid some authorities believing that they are a just of the embryone optic build and other considering them a part of the mesoblatic till which hes adjusted to the return (Fig. 10).

2 The downward growth of spindle index alcells of moles or nævi and melanotic neople mata are in direct continuity with the stratum germinativum of the skin (1)_k = 2/3/4 and 5)

3 The pigment bearing cells of normal skin and of the downward growths of moles or never are in the basal layer (stratum ger minitivum) and not in the subjacent connective tissue (Figs. 2-3, 4nd.4)

4 In accord with more recent observations of the histogenesis of epithelial neoplasmata they arise directly as a proliferation of the germinative or regenerative cells of the parenching of organs and not from either the differentiated cell or from cell rests

The cells of melano-epitheliomata may be ovil (Fig. 11a) or spindle (Fig. 11b) all cells do not contain pigment (Fig. 11 a. b. c)

In our series of 70 cases the condition arose, in both flat (Fig. 12) and pedunculated (Fig. 13) pigmented areas of the skin. The local growth may be discovered when there is no apparent invasion of the tissue subjacent to the pigmented nævus (Fig. 14). In the majority of cases however there is extension to the subjacent structures (Fig. 15). Pig ment may occupy a large (Figs. 14 and 16) or small part of the tumors (Fig. 15).

The pathogenicity of this type of neoplasm may be seen to best advantage in the following tables

prostatic gland and stomach.

this series shows no evidence of any relation to vascular endothelium 5 The condition is one of middle life

although it may be found from childhood to old age

6 An attempt at determination of the exact duration of the condition from its onset to a fatal termination has failed in this series.

7 There is no specific region of the skin which seems especially predisposed to the development of melano epitheliomata unless it is on the lower extremities which in this

series form the greatest frequency of location 8 Nævi certainly predispose to the develop-

ment of the condition o Metastasis is usually to the regional

lymphatic glands. 10 From an economical or practical stand

point melano-epitheliomata which arise in the skin have a high mortality

11 Melano-cpitheliomata or melanosar comata arising in the eye have a much better prognous than melano-epitheliomata arbing in the skin

12 From a therapeutic standpoint the pathologic history of melano-epithelioma clearly points to the necessity of an early diagnosis and a radical removal of the primary lesion and regional lymphatic glands.

13 From a prophylactic standpoint pig mented areas of skin, such as warts and nævi should be removed when these are in locations whi h are or have been subjected to injury

Ander claim that congenital ab ence of the kidney i an exceedingly rare anomaly in lates one case of the character. By iverigin is utable figure in a top intop ies the securrence of one nital incle kidney will one in 1817. Since the publicatin t More compilitin (508) he hel tound in the literature to cases it inch kidney which in iddition to the previously collected by Ballowitz and Moore made a total of 3. In the personal observation cited the left kidney renal art ry yem ureter and uprarenal body were ab ent He uggest that unquestionably nephrolith ia i ittended with peculiar danger to life in the of including where the ureter a occluded by calcula. It a important to remember that the vesic unctural orifice i cenerally absent on the id of the micine Lidney Cy to-copy hould be supplemented by ureteral catheterization where two ure teral entices exit ince in a mall percentage of cases of congenital kidney a rudimentary ureter a present. The importance of a angle kidney from a urgical tindipoint can scarcely be overemphasized. According to Anders advanced lesion of chronic nephritiwere found in thirty two of the tital cares per cent undoubtedly either teute or chronic nephritis in cases of renal agency. gives a less hopeful outlook than when de veloping under normal condition is bilit erally

Mayo states that ingle kidnes cours more frequently in males wherea the so-called horse-hoe kidnes i encountered oftener in females. Among thirty six coses of gross renal and uncteral anomalic observed in the Mayo clinic during a period of the vears twelve were of the hor eshoe variety and six of the single type.

Thomas reports a case of pelvic kidnes in a married woman of \(\tilde{\chi}\) disposed for recognition for pelvic becase. The vagins was about an inch in depth and no uterus was discoverable upon palpition. The pit tint had never men truated but uffered ovarian pain evers two month. A rounded tender miss the Le of an orange was detected in the left fossa. Then had been frequent attack of uninary frequency during the lat

Fig. 3 Case 2. Well-developed feminine tigure, alsence of vagina, terus, tubes, and ovaries single kidney located in peivia.

year The patient complained of abdominal pain, especially on the left side. Cvstoscopy showed the urethra and bladder normal. Left ureteral catheter arrested 2 25 inches from bladder right side apparently normal urine from both sides practically the same. Radiography after double injection of colloidal silver showed polvus of hydronephrotic kidney low in left bony pelvis. The ureter was 3 5 to 4 5 inches in length.

Cullen mentions a gul of seventeen who had never menstruated Inspection revealed absence of the vagins rectal examination disclosed a hard irregular mass filling right half of pelvis, thought to be uterus with retained menstrual fluid. Cociliotomy right pelvic kidney uterus and left kidney absent prolapse of tubes and ovaries in inguinal regions.

Bissell reports the successful reimplantation of a right pelvic kildnev in a female of 41 When observed the patient was about eight months advanced in uterogestation prema ture labor was induced, and after some delay an asphyxiated child delivered. One month later the pelvic kidney was reimplanted in its normal situation.

During routine examination of the body of a male of 30 who died of valvular cardiac discase Ward found no trace of the right kidney. The left kidney was twice the ordinary size with normal pelvi and ureter

At autopsy upon the body of a female of

Fig. 4. P elogram. Kidney in front and t. lift of sacrum hilum looking internally conve. border ext. mall

38 who died following a protracted debauch clazebrook found a single right kidney. There were two pelves and a single bifur cated urrier. The left kidney and urrele were absent. The right urreler below the bifurcation was normal in size and communicated with the bladder in the proper situation.

Stengel observed at autops) a longle kidney with two unterns and suggested that the surgeon in such a case after using the catheter might be deceived in thinking there were two kidneys and undertake an operation thus the only kidneys might be removed. In fact a case of thi character was operated upon by Polk of New York (1882) the pelvic mass removed being the right kidney. The pattern lived thritten days with complete anuma and at autops, it was I un I that this was the only kidney.

Mayer and Vellan cite a case in which there occurred suparietal traumatic inputure of a solitary right kidnes. No evidence of the left kidnes could be found although there were two ureters opening into the bladder in the normal situations. The patient died

Fig. 5. Cy togr m. sh wing theferen b. k.dn y with normal rounded outlin in distentio

thirty six hours after operation. Necrop viewcaled congenital absence of left kidney traumatic rupture of right kidney retro-peritoneal hamatoma acute nephritis kidney infarcts.

Secher describes the necropsy findings in a child without left kidney or ureter the supra renal gland being unusually large the genital organs were also asymmetrical. He states that while about three hundred cases of single kidney have been reported in the literature of the world these figures are misleading since distinction between total aplasia and atrophy is not always clear. The kidney was single in , of 8 150 cadavers examined ie once in every 1 104 cases. According to the records the anomaly occurs twice as fre quently in males as in females, and the left kidney is usually missing. The abdominal vessels and genital organs ordinarily display more or less deformity in such cases

TERATOGENESIS OF A HUMAN ATHORACIC ACEPHALIC ACAR-DIAC TRIPLET WITH NUMEROUS AGENESES

BY H. O. WHITE, M.D. LOS A CRUES CALIFORNI

From the Austrenical Laboratory of the officer of Physicians and Surposs, Michael Department of the University of Southern Cabican

T is with a sense of diffidence and more or less with a consciousness of temerity that I have consented to reopen a subject which has been illuminated by the contributions of the most distinguished mem bers of scientific research. A review of the voluminous literature on this subject could not fail to impress one with the weight which is attached both here and abroad to the coin ions of Ballantyne Schwalbe Halfeld, Keith. Thiersch, von Winckel Frankl, Stockard, and perhaps arouse the thought that the theme is well nigh exhausted. A further and more careful review of the literature on tera tology almost convinces one of the futility to contribute with entire originality hope however of eliciting a discussion which in some degree may help to enlighten our present knowledge this contribution is submitted

To Dr William F Smith of Calenno Cali forma I am grateful for sending to the ana tornical laboratory of the above menuoned institution a focus of considerable interest from a terratological standpoint and it, together with my previous investigations, constitutes a preliminary report upon which this communication is based

The fectus is a female, one of triplets of 6/2 months gestation with numerous agene ses, as is evidenced by the accompanying photograph and subsequent dissections. The other two fectuses were males and of normal

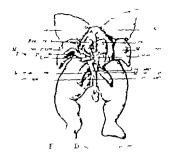

Fig. Photograph of specimen.

development. The monster is nine inches long and boars external evidence of the following aplacar head, neck, thorax upper extremities, and marked syndactylism of both lower extremities.

Careful dissection of the foctus disclosed complete acardia, asymmetry of the kidneys the left almost twice as large as the right absence of both adrenals internal genitals spleen, pancreas, and abdominal aorta. As to the alimentary canal, this was represented by a perpendicular tube in front of the verte bril column, terminating by the anal open ing in the normal povition.

It is agreed by all that in the human, only one embryo develops at a time, and it is equally agreed that twons are not infrequent Indeed, even triplets and less frequently quadruplets are developed

The most logical mode of twin production is due to a simultaneous fertilization of two ova, and also it may be brought about by the separation of a pertion of a germ plasm of a fertilized ovum into two parts development proceeding in each part independently to full maturity as is evidenced by expert mentation on the lower animals. It is reason able therefore, to assume that the latter mode of twin production must take place in the very early stages of development 1, e before the formation of the blustodermic layers, since at that time the ovum is nor mally already attached to the uterine wall and enveloped by the decidua capsulans. To my knowledg the literature is silent on the possibility of development of triplets or quadruplets by the separation of a fertilized ovum into three or four parts and although the result of my experimentation on the amphibian eggs does not yet warrant positive conclusions in this respect yet I entertain hopeful anticipation to be able to report the possibility of such mode of development in the near future

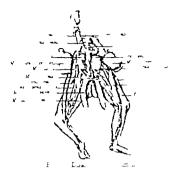

It is an infinible to the man a further may ter are alway if the ame set in they are developed it may income to the traction of the matter and to income the infinites. In the matter and to income which had more probable for period a separate retulated yum. Monite the quently is a needy to it tuper statum in the poeme to the poeme to the period of the

two ovalet we exist perform a wear to As a result we find along a wear to the more returned in varying times to development. Since the more retrieval, and the except the maliformation of the agreement. I am rather of the find that its presence was lived approximation.

It infinult hever to a pend the stage of that much level present for the moneter without admittine, that once created desection proves it an alardial and moreopic section, the runis disclose the presence of its normal tructure the moneter had derived its normal tructure, the moneter had derived its noun-hierent through the attachment of its unrith all cord either to a placenta common to the two the retuses of possibly to one of the placental peruliar teach normal ratu.

It is agreed by all that abnormal conditions of the uterus are among the causes contributing to retarded level pment malformations or even total destructions; if the coum

mu - n c ت سا⊄۔ nu author und bezie is The Mith ton 1 mind 1 response alom that in a na i'u vhal e tifer hit nai i m a premer in a imimbrune immuutub si an the vum L p L b - mpa -- d pri mara ran da fina and ea nha in e implantation and up-quilit level priest of the vum depend larges in a rable in htt n. r nintt n that implication is a estal has unquestronio a meat and tude to policie recorded arrayed development even mult muttin. The and tert implantati n mily probably expiring mily with Troumanyers rare ex pau in the enrall made are unally approximate onman match goldin in this b Timente the maternal of L ? the intravil in pace it also recalled a so prbafle ause

Again in e. a. I nearl that mounter are produced at a very early tale. I plea nancy the problems of implications and order process of implantation and order in a prementional membrane which has already

undergone histological changes may be en tirely responsible or at least largely a contributory factor to the causation of arrested de velopment.

That the defect may also be due to pri mary faulty maturation of the ovum is sug gested from the report of Ballantyne quoted by Bunbaum that ax deformed foctuses were born consecutively to one mother and all were of the same sex. And further that the malformation was not due to any abnormal conditions of the uterus, fortal membranes, or cord may be reasonably assumed from the state of preservation of the fortus in which, excepting the marked hypertrophy of the lower limbs, no evidences of intra uterine maceration or disinterstain could be elisted

That the enlargement of the lower lumbs was due to hypertrophy and not to ordema I am convinced from external observation and macroscopic dissection of the feetus.

The amount of hypertrophy of the limbs since the monster dled soon (ten minutes) after burth proves conclusively that it must have been present during intra uternoc life

As to the cause of this marked hypertrophy I venture to advance two main hypotheses first that it is due to a primary developmental hyperplana, and record that it is a secondary hypertrophy resulting from oversetrion. The first at once supposes that the structural precedes the functional abnormality due probably to a simple redundancy of growth. According to the second view the functional precise and causes the structural anomaly

It is a well-established fact that hyper trophy from repeated forcible contractions us a property of all muscle tissue voluntary or involuntary and further that tendency to normal hypertrophy is greater in the former than in the latter

There is no proof to the contrary that hy pertrophy may occur is wirer under the same conditions as it does after birth, and owing to the extreme activity of the processes of nutrition and growth is ulere it is quite possible that hypertrophy could probably take place more readily and to a greater degree is wirer

Again for the proper functioning of all organs perfect harmon; of co-ordination is indispensable and a disturbance of coordination of any magnitude is apt to exage gerate exertion. When, however I conjecture what the nature of such disturbance of co-ordination can possibly be, I fear that I am perhaps getting into a region of guesang However I am tempted to advance the suggestion that it is possibly an intra uterine

developmental neurosis. Assuming now as I do assume, that a functional cause is responsible for the hypertrophy of the lower limbs that cause I believe to be a disturbance of normal co-ordination and, although I do not wish to lay too much stress upon this functional cause yet no other adequate scientific suggestion has ever been advanced

As to the causes of aplasia various scientific opinions are entertained

Birnbaum is of the opinion that faulty and imperiest development of one-half of a twin blastoderm is the cause of malformations.

Schwalbe on the other hand reasons since it is accepted by all that malformations occur at a very early period of development, and since they may be caused by primary developmental defects as well as secondary degenerations hence special investigations must be undertaken separately for every malformation, and he adds that partial destruction of one germ may be considered as a cause, but he does not suggest how that partial destruction are struction may possibly be brought about.

Von Winckel maintains error of development as a cause which must occur before the development of the circulatory system. Imperfect or arrested segmentation is also suggested as a cause

F P Mall, quoted by E I Werber holds that faulty implantation of an ovum in the wall of a diseased uterus, together with the inadequate nutrition arising therefrom, is responsible for defective development.

Ö Hertwig, from his experiments with amphblian eggs, subjecting them to the action of a weak solution of sodium chloride, suggests that monsters in the human may possibly be due to the presence of certain poisons such as alcohol or toxins in the blood of the mother

C R Stockard in a series of experiments with fish embryos, subjecting them to the

action of different chemical substances proved beyond the shadow of a doubt that not only in the verv early stages of develop ment but even in the late stages deformities may be artificially produced and although those deformities are evidently caused only by subjecting the eggs to various chemical substances yet he justly admits that this may not be the sole cause of such defects and that any factor capable of influencing the developmental energy could possibly induce similar results.

E I Werber from his very recent researches on the eggs of fish besides corroborating the indings of Stockard suggests the possibility of some products due to pathological conditions of metabolism as a teratorenic cause

It will be noticed that all agree on maltorna tions occurring during the very early stages of development. While I fully coincide with Schwalbe that for each malformation a special investigation should be undertaken vet I venture to maintain that for monsters like the one discussed in this communication one is forced to admit not only the possibility but a high probability of some factor at an early stage of development to be entirely responsible for the cutting off—as it were of the anterior half of the embryonic rudiment.

That mechanical forces are capable of producing marked influences on early or even late developing ovar or embryos is evident from the experiments of Lewis who produced typical monsters by mechanically injuring the anterior part of the embryonic shield in the developing egg. And also though not necessarily in every case mechanical influences applied to developing eggs during late stages were equally productive of the same results.

On the other hand, Spemann successfully produced monsters by constructing the seg menting eggs with delicate fibers

May it not be reasonable to suggest, there fore that some such mechanical cause under favorable circumstances may produce an intra uterine constriction of the evum in early or late stages of development in the lower mammals and also in the human

The most frequent variety of human mon sters is holo-acardiac acephalus Taruffi was able to collect 108 cases and Foerster states that acardiaci formed 18 per cent of his collected cases. In this class of monsters the entire antenior half of the body above the umbilicus is absent, and only rarely are rudiments of the missing structures present.

The morphological appearance alone of such monsters suggests the possibility of an intra uterine factor in the nature of a constriction, to be a responsible cause. That constriction I believe to occur in the aminon at an early stage of development, when the separation of the embryo from the blasto-derm takes place in the form of an hour glass contraction and as I have intimated above eutting off the anterior half of the embry on it disk. I am advancing this as all hypothesis and am inclined to believe that in future I shall be able to substantiate this hypothesis experimentally.

If now we admit the possibility of such constriction, the various aplease in this or any such similar monster are quite apparent and do not require any further elaborations.

Careful dissection of this monster and its from the usual manner of distribution of the blood vessels in such monsters as first pointed out by Hempel and quoted by Schwalbe that the blood flows to the acardiacus through the umbilical arteries and returns through the umbilical veins. It must be remembered that this abnormal circulation is the product of imperfect development and not the cause.

As to the aplasm of the uterus tubes and ovaries it is well known that the gental glands become the ovaries the cephalic por tions of Mueller's ducts become the fallopian tubes, and the caudal portions since they are situated close to one another become even tually confluent into a single tube from the proximal part of which the uterus develops and from the distal the vigina.

From their embryology aplasms or malformations of these organs are easily under stood. Thus while malformations of the internal genitals may be the result of partial hindrance from growth of portions of Mueller's ducts symmetrically or asymmetrically aplasia must be due to complete hindrance from growth of Mueller's ducts or may be

entirely undeveloped

In this monster however since the external genitalia are present, particularly the vacina. it is evident that only the caudal portions of Mueller's ducts participated in the process of development, the cephalic portions disappear ing or falling to develop entirely

To Dr Albert Soiland I am very grateful for the preparation of the photograph, and to Professor Charles W. Bryson, Dean for his encouragement and facilities afforded

to conduct research work.

A CONTRIBUTION TO THE ETIOLOGY OF CANCER OF THE ŒSOPHAGUS AND STOMACH

B WILHELM LERCHE, M.D. FACS, S. P. V. MIDOGROT

Y the ancient Roman physicians the asophagus was called gula or atomachus, by the Greek physi cians cesophagus Cancer of the cosophagus was probably first described by traien in the second century under the name of carnositas stomacks. The Arabian physician Avengour (1) 1070 to 1162 had good knowl edge of cancer of the resophagus. He origi nated the method of feeding through a tube patients suffering with this disease and he also introduced the method of rectal feeding in such cases.

EIIOLOG1

The discussion of the ethology in this paper is devoted particularly to the consideration

of a local predisposing cause, which the writer thinks important. Cancer of the cesophagus was formerly considered a rarity and in French statistics for the Seine Depart ments between 1830 and 1840 only 13 cases were found in 0 118 deaths from cancer the Wuerzburg statistics by Virchow (2) 1851 to 1855 the ocsophagus was not counted among the organs frequently affected by cancer In 1901 Fellchenfeld (3) on the other hand speaks about the remarkable frequency of cancer of the cesophagus.

HEREDITY

Bainbridge (5) sums up the question of heredity in cancer in general as follows Heredity has been shown to play a rôle but not one to cause anxiety Kraus (4) in discussing cancer of the ce-ophagus says that heredity plays no important part

GEOGRAPHICAL DISTRIBUTION

It has been stated that natives of the cx tremely cold regions and those of the tropics and subtropics are practically immune from cancer. Closer investigation however has shown that cancer is found among the Feki mos as well as in the natives of the tropics and von Hansemann says that there i no kind of malignant growth among us that does not occur in the natives of the tropics, and vice users.

Trolard (6) during six years practice in the French hospital in Safti. Moracco where there came about 100 patients daily had only seen one case of cancer of the digestive tract (a case of cancer of the liver). He says that it is extremely rare among the Berbers. This has been the experience of others in Egypt and other parts of northern Africa.

In Sutherland's (7) report from Lahore India, he states that among 43,412 patients admitted to the hospital between 1892 and 1903 there were 2 cases of cancer of the esophagus and none of the stomach in 329 cases of carcinoma. Sutherland remarks that cancer of the stomach 18 rare

Niblock (8) tabulating the records of malignant tumors in Madras General Hospital from 1892 to 1901 found 4 270 cases Of these 970 were case of carcinoma of which 21 were of the stomach and 3 of the cesophagus

On investigation made in the Portuguese colonies (73) a total of 4 cases of cancer of the stomach and 5 cases of cancer of the ecsophagus had been recorded in various hospitals some records extending back 13 years.

Cook (9) has seen cancer of the esophagus among the natives of Uganda Central Minea

Maxwell (10) found that in 11 ∞ patients in Changpoo Hopital in South China there were 54 cases of cancer of which 8 were of the esophagus (7 males one female) and 2 of the pylorus

At the hospital for Chinese in Tartar City Pekin Foulkes (11) found a fair number of cases of cancer. He mention one case it cancer of the assorbagu

Meldorf (1) has reported cases of cancer of the ecophagus and stomach in the natives of Creenland

Renner (13) save that in the negroes in secret Leone who a aborigines are rather free from eineer there I increase in the cancer rate when they adopt the white man's due and mode of living. In 453 cases admitted to the hospital from 1870 to 1000 there were 20 cases of malignant growth in 10 103 cases admitted from 1900 to 1000 there were 20 cases. One case out of the 40 was cancer of the assophagus. No case at cancer of the tomach is mentioned in the report

In the temper it climate which correspond to the so-called civilized part of the world cancer is frequent but the statistics show that within this zone the death rate from cancer varies considerably in the various countries. Thus according to Williams (14). Switzer land has the highest cancer rate with 13 deaths per 100 000 living inhabitants and Hungary one of the lowest with 39 deaths per 100 000 living.

The relative frequency with which the various organs are affected by cancer varies in the different countries.

It is sometimes seen that cancer occurs more frequently in certain parts of a country—thus according to Haeberlin (15) cancer of the stomach was the cause of death in

3 per cent of all deaths in northeast Switzerland 1 5 to 2 per cent of all deaths in the western half of Switzerland

r per cent of all deaths in the southern part of witzerland

I have roughly figured out on the basis of

the statistics of Nencki (16) that cancer of the cesophagus was the cause of death in

o 7 per cent of all deaths in northeast Switzer land o 46 per cent of all deaths in the western part of

Switzerland
o \$4 per cent of all deaths in the southern part of

Switzerland.

Of all cancers in men, in the District of

Wangen (Canton Bern, Switzerland) 36 per cent were of the œsophagus. Kolb (17) found that in Bavaria cancer of

Kolb (17) found that in Bayara cancer of the cesophagus was more frequent in the north ern part than in the southern part.

In Normandy France, the rate of cancer of the stomach was very high in the south of France it was very low

SEX

Men are much more liable to cancer of the gullet than women. Table I shows the ratio of male to female deaths from cancer of the gullet in various mortality statistics and in some collections of cases.

In Table II is shown the percentage of can cer in all deaths, and the percentage of cancer of the ecsophagus and stomach in men and women in the post mortem material of various authors.

In Table III is seen the proportion of deaths from cancer of the esophagus in men and women in the autorsy material of various authors.

men in the autopsy material of various authors.

In men carcinoma of the stomach is the first in order of frequency in most cancer statistics, and in some statistics cancer of

AGE

the resophagus comes second

Carcinoma of the cesophagus is a disease of middle and old age. It is comparatively rare under the age of forty

According to Philipp (29) no case has been reported as occurring in childhood, and the youngest cases on record are probably—

Heiman case, 9 years old Mampell case 20 years old Stewart case 3 years old Stevyania case, 24 years old.

Table IV shows the age and sex incidence of malignant tumors of the cesophagus and stomach based on the national mortality returns 1001 to 1003 for England and Wales.

SITE OF CANCER IN THE ŒSOPHAGUS

Any part of the cesophagus may be the ute of cancer as shownin Table VI. The question as to what parts of the organ are most fre quently the sites of cancer is apparently as unsettled today as it was in the past century some authors claiming the upper third some the middle third and some the lower third. Only on the basis of large statistical material can this question be settled.

In Table VII I have brought together all

been arranged according to nationality that in the English and French groups the upper end is the part of the casophagus most frequently involved by cancer while in the other groups the lower part is affected in the majority of

Koenig (54) in 1880 in discussing the question of the relative frequency of the sent of cancer in the upper middle and lower part of the cesophagus and reterring to Mackensie's (31) cases said. Can it really be that in England cancer of the exceptagus is so much more frequent in the upper third?

It has been my experience in croophageal work that patients who locate their trouble in the upper end of the croophagea are apt to consult the throat specialist while those who locate their affliction in the lower part of the organ will consult the general practitioner the surgeon the internist, or the atomach specialist hence the latter cases become scat tered among a larger number of consultants and are not reported because each one gets only a small number of cases. This observation seems to be borne out here, because if the cases published by the throat specialist are segregated the result is entirely different, as seen in Tables VIII and IA.

Note the striking difference between the groups of Newman, Turner and Rawling and the St. George Hospital, and likewise between Guisez and Lamy Rawling says that he does not believe that cancer in the upper end of the guillet occurs in more than 10 per cent of cases. It seems reasonable to

assume that if a larger number of autopsy reports from large general hospitals in England and France come forth it is likely that they will show about the same results as those of the other European countries.

Although the number of cases here brought together may not be sufficiently large to settle definitely at what part of the cosopha gus cancer most frequently occura, it is highly probable that Table IA, gives the correct aswer representing as it does the clinical and post mortem records of large general hospitals and clinica in the various countries.

Assuming therefore that Table IX gives the true expression the question immediately presents itself. Why does cancer occur more frequently in the lower part of the cesophagus than in the upper? For the sake of compari son I have analyzed 108 cases of cicatrical strictures of the arsonhagus caused by swal lowing corrosive fluids, and found that 18 per cent occurred in the upper part 298 per cent in the middle part and 52 per cent in the lower part of the organ. This corresponds exactly to the seats of predilection of cancer of the cesophagus. The question is whether this is a mere coincidence, or whether there is some definite physiological law that determines these so-called seats of predilection?

In a previous paper (55) I have shown that the relative frequency of the seats of cicatricial strictures of the ocsophagus following the ingestion of corrodive fluids increase from above downward for the reason that the speed of the peristaltic wave which propels the cesophageal contents decreases from above downward, thus permutting the corrosive fluid to remain longer in contact with the cesophageal mucosa in the lower parts, with consequent deeper insult. In the lower thorack part where the content comes to a momentary stop the destruction is usually the most extensive and this part is the most frequent seat of cicatricial strictures. The upper end which is the narrowest part of the esophagus, and where the peristaltic move ment is swiftest, often escapes entirely

The narrowest part of the esophagus is at the mlet, and from there to the cardia the lumen increases (with slight constrictions at certain parts) so that the statement found in most textbooks—that cuatricial structures as well as cancer of the desophagus are found at the physiologic constructions inferring that the latter are responsible for the pathologic conditions mentioned—does not seem to have sufficient foundation. Furthermore in animals we find physiological constrictions and yet in these cancer of that organ is extraordinarily rare.

It we now examine the stomach from a similar viewpoint we find that in regard to the parts of the organ most frequently affected by ingested corrosive fluids it has been observed that when a smaller quantity has been swallowed the effect is most frequently seen along the lesser curvature and in the pyloric region particularly in the latter

Thus Hollman 1,00 describes a specimen of a torach in which continuous, to ro mm which treaks caused by swallowed hydrochloric acid were found along the lesser curva turn from the circlia to the pyloric region. In the latter rigion the area of destruction was mot extensive while the rest of the stomach with the exception of a few insignificant sears in the fundus was normal. This corresponds to the indunes of Ernest and others.

According to Aschoff (74) lesions from swal lowed acids are especially found along the lesser curvature

It seems apparent therefore that corrosive fluids like other fluids swallowed ordinarily pass from the esophagus along the lesser curvature of the stomach to the pylonic region where the corrosive fluids remain for some time

The reason why the fluids pass along the lesser curvature which I have called at tention to in a previous paper (68) is that the inner oblique muscular layer of the stomach contracts in such a mainter as to bring the cardia and the pylone part closer together and to make the gastric mucosa form a trough or canal into which the fluids coming from the easophagus are directed. This canil becomes so to speak a continuation of the esophagus and although it has already been given various names it seems to me that the designation gula gastrica or the gastric gullet would be quite appropriate. The function of this canal has been demonstrated in the dog by

Cohnheim in the horse by Ellenberger

In experiments on certain animals it ha been observed that fluids are spurted into the *tomach with considerable force which i likely due to the contraction of the epicardia If this is also the case in human beings, the speed with which the fluid travels would probably be greatest at it emanates from the cardia, and would decrease toward the pylor ic region with the same consequences that we have seen in the œsophagus namely that the upper part may escape while in the lower part where the speed is slowest and especially in the pyloric region where the fluid comes to a stop the injury is mo t extensive when cor rosive fluids are taken. The pyloric region is the part of the stomach mo t frequently and usually most severely affected by the corrosive fluid at times it is the only part affected the rest of the stomach a well as the xsophagus escaping entirely

Thus in 50 post mortim cases collected by Quanu and Petit (3) in which the stomach was severely damaged from the ingested corrosive fluids causing death the esophagus was simultaneously affected in 34 of the cases In 20 cases or 33 80 per cent the esophagus was not affected. In 14 less severe cases that had been collected by the same authors and that had survived the effect of the poison and had been operated upon tor obstruction in the pylone region caused by the corrosive fluid, the esophagus was simultaneously affected in only 6 of the cases while 18 cases or 82 3 per cent had escaped.

It is of interest to note that in the 59 post mortems in which the effect of the corrosive fluids caused death the duodenum was only affected in 23 8 per cent. In none of the 34 cases of the second group was the duode

num affected

In cattle similar observations have been made. Lichtenstern (58) found this in the post mortem examination of 5 cows that had to be slaughtered on account of illness following the accidental feeding of hot fluid fodder. The autopay appearances were the same in all namely changes contined to the omasum or third stomach, while in the rest of the stomach and esophagus there were no changes except in Cases i and where parts of the tongue pharvax and α-sophagu were also

found affected Cases 1 and 2 stood nearest to the end where the fodder was poured into the trough. The function of the omasum is to dehydrate the food, and fluid foods pass directly into this part.

In regard to the most frequent sites of can cer in the stomach, it may be said to be a repetition of what is true of cancer and clea tricial strictures of the essopharus namely

there is an increase from above downward, following what has been referred to as the continuation of the exophagus, "the gastne gullet. In other words the cardia, the lesser curvature, and the prepyloric part are the regions of the stomach most frequently affected by cancer and Table \(^1\) shows that this region was affected in \(^1\). Por cent.

TABLE X.— SHOWING THE SITUATION OF THE TUMOES
IN 1,300 CASES OF CAMCER OF THE STORACTI COL
INCTED BY WELCH (40)

***	per com per com per com per com per com per com per com per com

In Table XI, I have collected some more recent groups of autopsy cases, which show the same namely 78.88 per cent. It will be noticed that in the latter table the percentage of cancers of the pyloric region is somewhat lower and the percentage of cancer of the lesser curvature is somewhat higher than in Table X.

The exact starting point of the growth may be impossible to determine at autopsy but you Mielecki (77) found in his material of 156 cases of cancer of the stomach that the center of the carcinomata occurring in the pylone region was several finger breadths away from the pylone sphincter the latter being usually free.

Clinically according to Mikulica (62) the leaser curvature near the pylons is the pin man; starting point in most cases of cancer ventriculi—probably in 40 per cent, which would correspond to the pyloric vestibule and the pyloric canal

Von Hacker (50) in 100 cases of cancer of the esophagus found that the lower part of the organ was affected in 49 62 per cent. Of these cases 27.49 per cent were found above the hintus, while only 22.13 per cent were at the cardia

It would seem then that just above and in the epicardia, and just above and in the pylor ic canal, which probably are the parts regulating the evacuation of the œsophagus and stomach respectively are the favorite sents of cacatrics from ingested cornorive fluids, because there the fluids remain the longest in contact with the mucosa. The same parts are also the favorite sents of cancer (Fig 1)

Cancer of the stomach occurs somewhat more frequently in men than in women, but in large statistics the difference is small thus, in the statistics of Martin (63) of 20 000 cases 58 per cent were men.

ACTE

Cancer ventricul is a disease found most frequently between the ages of 40 and 70. It is comparatively rare before forty and after seventy. A number of cases have been seen in children, and it has been observed in the newborn. (see Table VII)

CANCER OF THE OSOPHAGUS AND STOMACH IN ANIMALS

Investigation has shown that cancer is not a disease confined to man because it has been demonstrated in nearly all species of vertebrates including manne fish living in a state of nature. The Imperial Cancer Research Fund (64) of London, in its reportation to the statement that the probability is that when the full facts are known the recorded incidence of cancer at all ages will

stomach.

approximate in cattle and in mice that at all ages in the human subject

The statement in regard to the cattle wa apparently tounded upon the reports of Veterinary Inspector Trotter who in 190 found , cases of mulignant new growths in 62 03, cattle of all ages and in 1903 found 131 cases of malignant new growths in 47 362 cattle of all ages slaughtered in Clasgow Nearly all of the cases were found in old cowsimported from Ireland

The Research Fund also reported 3 specimens of cancer of the stomach in cows ex amined by them in 1903. On the basis of these reports it has been stated in more recent hiterature that cancer of the stomach is com

mon in cattle

In the tatistics of Sticker's (6.5) based upon the reports from the Berlin Neterinary school and the Berlin and the Vunnich Statistic Pathologic Institutes for a period of 22 years together with extensive search of the literature there were

- 8 ages of cancer of the stomach in horses
- I case of cancer of the resophagus in a horse
 I are of cancer of the stomach in cattle
- ase of cancer of the stomach in a dog

schmes (66) has recently reported a case of cancer of the stomach in a monkey 8 to lovears old which corresponds to the age of 10 years in man

To the United States Bureau of Animal Industry during the months of November and December 1914 and January and February 1915, there had been reported 94 cales of carcinoma and sarcoma in a total of 350 000 cattle killed or 0 004 per cent. There was no information given about the ite of the tumors. The number of canners or old cows from the age of 8 to 15 years or older killed amounts roughly estimated to about 25 per cent of the total in some slaugh ter establi himents—probably in all of them Not infrequently and for various reasons

Not infrequently and for various reasons the viscera are condemned as food products and are disposed of without complete inspection. As uch viscera might harbor malignant growths nothing conclusive can be drawn from the above reports. According to the experience of meat inspectors, however

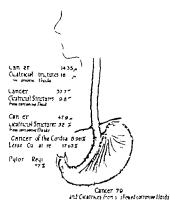

Fig. Schemat draing hing the uner bind e muscle laver if the stomach indithe gastri gullet also the relatified in with bin a end locatrical in ture occur in the anous part of the easy plagus and

cancer of the stomach in cattle mu t be very

In 64, wild animals under observation in the New York Zoological Park 16,1 during tive years but one case of true neoplasm occurred namely a sarcoma of the ovary in a raccoon dog Seven hundred forts four of these animals came to complete autops.

With the exception of the one case in a horse mentioned above I have found no report of cancer of the esophagus in animals in the literature

SLADVARA

A brief summary of what has been said so far in this paper shows that —

1 Cancer of the resophagus is exceedingly rare in animal

Cancer of the toma his rare in animals.

3 Cancer of the resophagus and stomach
is comparatively rare in the natives of the

tropical and subtropical countries
4 Cancer of the esophagus and stomach

4 Cancer of the esophagus and stomach is common in certain countries in the temper ate climate zone, inhabited by so-called civi lized man

- Cancer of the ersophagus is much more frequent in men than in women
- Cancer of the stomach occurs with almost equal frequency in both sexes.
- Cicatricial atrictures of the resorbagus and the stomach, from swallowed corrosive fluids particularly form at certain parts of those orunns and for definite blassological reasons
- The favorite sites of cancer in the cesophagus and in the stomach correspond exactly to the favorite sites of the cicatricial strictures in those organs.

It seems, then that although any vertebrate organism may be the subject of cancer and that cancer of the cesonhagus and stomach may occur in any race dvalued man in particular is peculiarly liable to cancer of those organs. Why?

Naturally the food and drink passing into the oesophagus and stomach suggest them selves for investigation, and a great many articles of food and drink - particularly meat and alcohol - have been put down by various writers, as predisposing causes of The importance of some of these cancer articles has possibly been overestimated on the other hand some authors are inclined to go to the other extreme and disregard food and drink as possible predisposing causes Mackenzie (31) in 1880 said century and a half ago Van Swieten was disposed to attribute the origin of cancer of the gullet to swallowing very hot fluids, especially coffee which at that time was coming into general use. This view however was no doubt erroneous and was strongly opposed by Perhaps the view of Van Swie Morgagni ten was not erroneous after all.

It is said that the \ rays have been responsible for the production of cancer of the skin in some cases and that in the wearers of Kangri baskets in the smokers of short clay pipes, the chronic irritation produced by those habits has been responsible for the growth of cancer

There is a reason why cancer of the assoph arus and the stomach is so common among the inhabitants of certain countries in the temperate climate zone.

There is a definite reason why 79 per cent of all cancers of the stomach occur in the small area comprising the cardia, the lesser cur vature and the prepyloric region.

May not chronic irritation caused by the large quantities of hot fluids habitually con sumed by civilized man, and the mechanism directing the fluids into the gastric gullet be responsible?

That cicatrices from swallowed corneive fluids are especially found along the lesser curvature points to the possibility that fluids may have something to do with the fact that most of the tumors of the stomach are found in this very region - the high was of the fluids.

Habitual local application of undue heat. causing chronic irritation, appears to be inducive to malignant changes of the trasues in other parts of the body may not this also he the case in the atomach? If this view is correct it carries with it the conclusion that the hot fluids are also the main predisposing cause of cancer of the cesophagus

When I say hot fluids. I do not mean to the exclusion of bot solid or semi solid food but as these latter are more or less masticated and mured with saliva, the temperature of such a bolus may be somewhat reduced by the time it reaches the assophagus and stomach. Furthermore solid food is probably not di rected along the lesser curvature to the pyloric part, the area in which the majority of gastric cancers are found

The hot fluid, on the other hand, is quark), swallowed and on entering the cesophagus passes swiftly along the upper part of the or gan slower through the lower half and after coming to a momentary stop above the epicar dia is propelled into the stomach, where it passes along the gastric gullet, as outlined and comes to a halt in the prepyloric part. As the fluid travels swiftly through the cesophagus its temperature has probably not become much reduced by the time it reaches the highly specialized epithelial lining of the stomach.

The prinking painton of the Searchen of the pathwings of the leaser degreents I have paint (8) were lost or very cold drank may be retain the emosphages for the specific central the mosphages for the specific central terms of temperature leasts the measure of temperature leasts the measure when seemely

Fluid like coffer ter soups etc. habitually taken at a temperature that would be unbearable to the kin and the frequent travel of very hot fluids through the cesoph agus and along the galtric gullet may have the same effect upon these part, as the heat from the Kangri backet ha in the skin of the abdomen of the natives of Ka hmir India (60) These people wear a balket containing a mall vessel with burning char coal next to the kin of the abdomen during the cold weather and the chronic irritation from the heat a considered the cause of the epitheliomata of the kin of the lower abdomen and thighs so trequently seen among them

As mentioned before in this paper men are more hable to cancer of the re-ophagus than women - probably about in the proportion to 1 On the other hand carcinoma of the tomach occur with almo t equal fre quency in the seven although somewhat more frequent in men

How can the phenomenon be explained I think by the difference in the mode of drinking in men and women. While men comm nly take large swallows and often drink hurnedly women almost invariably ip fluids and eat and drink more slowly (on equently in women only a small quan tity at the time passes swiftly through the ces phagus. When the hot fluid reaches the tomach however it strikes the highly pecialized epithelium of less resistance than that of the resophagus and coming to a stop in the prepyloric region, the benefit of the maller swallow which saves the esophagus is eliminated and both sexes are practically on the same footing. The epithelial lining of the esophagus covered as it is with mucus may escape the effect of the heat in a small swiftly moving quantity of fluid while large swallows taken at short intervals do damage by longer exposure

This is well illustrated by the effect of a small quantity of corrosive fluid swallowed a mentioned earlier in this paper which will often leave the entire coophagus intact and only attack the lesser curvature and the prepy lone region or the prepylone region only

Thus it may be said that the pathology of the lesser curvature indicates that the physicI grad function of the gatric gullet e rding to the theory of Retziu. I correct Viewer a it may be said that the phy io logical function of the gretne gulket tend t) upport the hypothesi that fluid au ing chronic irritati n particularly hot fluid may be responsible for the lesion. If the part of the tomach a well a that t the exphagu

Judging fr m the cale of Petit and Ouenu the pyloru ordinarily does not permit the immediate passage terrosive fluid into the duodenum. In the Spercent of the reof the fir t group in which the du xlenum wa affected the corro is a fluid had probably ever whelmed the pylonic regulating apparatu- and paralyzed it to uch an extent a to interfere with its normal action

According to Mueller () the temperature of fluids entering the tomach much above cr much below the body temperature 1 quite rapidly modified and the fluid are not permitted to pay into the duodenum until they have attained a temperature approximately that of the body

The pars pylonical therefore is apparently also an apparatu of protection for the deli cate duodenum. The latter organ ha the benefit of the protecting and modifying function, of the stomach and it receives the con tents of that organ in a condition for which it is physologically adapted thu e-caping the chronic irritation to which the a sophagus and tomach are exposed. That this has something to do with the relative treedom from cancer which the duodenum eniov seems highly probable

In light of what has just been said it is of interest to compare the cancer tatistic of the north and south of Europe taking for examples those of Norway and Italy Norwegians are one of the healthiest races in the world according to the death rate during the last decade. The cancer rate however is comparatively high namely 9 per 100 000 population

Recent statistics by Munch Soegaard (,0) how that cancer of the stomach in the rural districts of Norway is 6, 3 per cent of all cancers or 70 per 100 000 population.

Uniort nately the de th rat or cancer of the oreophist is not pertied in here tabutes by it sed there och one

It is interesting to note that cancer of the female generative organs in the rural districts was only 55 per cent of all cancers which is unusually low (see Table VII). It is pointed out by Soegaard that cervical liceration must be frequent, as the peasants usually have large families. On the other hand gonor rheal infection is practically unknown among them.

The cancer rate in Italy is one of the lowest in Europe it was 52 per 100 000 living in habitants in 1800 (14) An analysis of the statistics (71) shows that cancer in general is less frequent in the south than in the north This is particularly the case with cancer of the gastro-intestinal tract, and especially of the esophagus and stomach. Cancer of the resonhagus and stomach combined, was 14.5 per 100 000 population the north and the south of Italy are considered separately however we find that the nine northern compartiments show 10.8 per 100 ooo living inhabitants, while the seven south ern compartimenti including Sicily and Sardina showed only 5 3 per 100 000 popula tion of cancer ventriculi and resophage com bined, or nearly four times as many in the north as in the south. The death rate from cancer of the female generative organs in Italy was 8 per 100 000 population but of this the north showed 0.8 per 100 000 inhabitants while the south had 5.8 (Table VIII) The difference between the death rate of the north and the south of Italy m cancer of the female generative organs is therefore not nearly so striking as the dufference between the north and the south in regard to cancer of the essophages and atomach.

The death rate from cancer of the female generative organs in the rural districts of Norway was 6 per 100,000 living inhabitants, which is equal to the lowest in Italy In other words, while cancer of the stomach in Norway according to the statistics, was several times as frequent as in Italy cancer of the other organs occurred with about equal frequency in both countries. In Norway (72) the consumption of meat and alcohol is low the consumption of coffee is excessively high (12 25 pounds of coffee and o 12 pounds of tea per head per annum). In Italy (72) the

consumption of coffee and tea is very low (1 or pounds of coffee and 0 005 pounds of tea per head per annum) The climate of southern Italy is nearly tropleal.

In the Norwegian rural districts hot coffee in large quantities, is taken four to five times a day. The same is said to be the custom in the northeast part of Switzerland, and in certain parts of the latter country hot coffee with brandy is said to be a favorite drink

In the first part of this paper we have shown the percentage of cancer of the stomach and cancer of the ceophagus in all deaths in various parts of Switzerland. In the south of Switzerland the population is almost entirely Itahan in the western cantons the French predominate and in the northeast part the Germans. Again we see that the Italians are less prone to cancer of the cesophagus and stomach.

On the whole cancer of the exophagus and stomach seems to be much less prevalent among the natives of the tropical and subtropical countries probably for the reason that a hot climate is inducive to frugality in diet in general and therefore the habit of taking large quantities of hot fluids is less likely to form

CONCLUSIONS

- r Cancer of the exophagus and stomach is peculiarly prevalent among the inhabitants of the temperate climate zone
- 2 The relative frequency with which coat incial strictures from swallowed corrosive fluids occur in the various parts of the escophagus increases from above downward in other words, the widest parts of the escoph agus are the most frequent sites of such artictures—and for physiological reasons.
 - 3 The distribution of cancer in the croonh

agus corresponds to that of the cicatricial strictures from swallowed corro ive fluids and in all probability for the same physiologic cal reasons

4 Any part of the resophagus and stomach may be the starting point of cancer with the exception of the pylonic sphincter which rarely seems to be the primary focus. The organ immediately beyond namely duodenum is practically immune from cancer The reason for the two latter phenomena probably that the ingesta do not reach the pylonic sphincter until they are properly modified

. In view of the foregoing conclusions it seems logical to look to the ingesta of civilized man for the source of chronic irritation, which lead, to malignant changes of the asophagu.

6 The uppo ition that swallowed fluid after emanating from the cardia are directed along the ga true gullet to the prepylone region is strongly upported by the fact that the cicatrices from smaller quantities of mallowed corrosive fluid are usually found along this path

Seventy nine per cent of cancer of the stomach are also found along this path the cardia the La tric gullet

prepyloric region

8 As cancer of the tomach follows the highway of the fluid it seems logical to assume that ingested fluids in particular may be respon ible

- Alcohol and other irritating fluids prob ably play a part but in the opinion of the writer hot fluid 40 universally taken throughout the temperate climate zone in the form of coffee tea soups etc and giving nee to chronic irritation is the main predisposing cause of cancer of the coophagus and stomach
- 10 Cancer of the assophagus occurs les often in women than in men because women drink more slowly and take smaller swallows which pass quickly through thus saving the excephagus while the less resistant mucosa of the stomach where the fluids come to a stop is more equally exposed in both sexes
- II The fact therefore that the ratio of cancer of the æsophagus in men and women 18 3 5 to 1 while cancer of the stomach occurs

with almost equal frequency in both seves points strongly to hot fluids as the ini portant predi posing cause

This is turther ubstantiated by the results of a companion between the cancer stitistics and the habit of the people in the north and south of Europe by the relative freedom from cancer of the ocsophagu and stemach enjoyed by the aborigine of hat climates and the extrem by rare occurrence of cancer of the ex-ophigu in inimal

RUPTURE OF BLADDER ASSOCIATED WITH FRACTURE OF PELVIS

WITH BIBLIOGRAPHY AND REPORT OF ONE CASE

BY E. P. OUAIN M.D. FACS BISMARCK, NORTH D. & TA

PROGNOSIS in intraperitoneal rupture of the bladder is as a rule other very good or very bad. The injury is either promptly diagnosed and successfully repaired or it is unrecognized or unsuccessfully treated and death from peritonits follows in a tew days.

In extraperitoneal rupture death does not usually come within the first three or four days even if the treatment has been ineflicient or absent. The urine infiltrates through the soft parts in front below and behind the bladder and eventually comes to the surface through the inguinal canal through the femoral opening in the perineum or the prevesical space and is then often afforded an exit by incisions through the skin urine may not extravasate into the tissues The extravesical tension may become so great that a large amount of urine accumu lates in the bladder and is thence exacuated normally or withdrawn by catheter nosis so far as immediate mortality is concerned is not therefore as bad as in intra peritoneal rupture. In point of morbidity however the unter believes with Fuller that most patients with extraperatorical rupture of the bladder are left senously invalided for hfe

The invalidism is due to several cruses The extravasation of urine is followed by infection suppuration and necrosissloughing may become very extensive and in case of recovery lead to cicatrization contraction and loss of normal function of ureter bladder urethra or sexual mechanism Another cause of more or less permanent disability is fracture of the pelvis which very often is associated with ruptured bladder The bladder is perforated by a splinter of the fractured bone in most instances. But the two accidents fracture and bladder lacers tion may occur separately though from the same accident, the overfilled bladder ruptur

ing from a continuition of the ferce which caused pelvic fracture with wide separation of the fragment. This und ubtedly took place in my own cust reported below. Even if the fracture 1 not in contignity with the bladder wound the extrivisated urine is likely sooner or later to invade the 1te of fracture and to complicate it by adding in feetion.

Bladder laceration and pelvic fricture present for treatment two separate and very grave lesions. A study of the authorities shows a unit smuty of opinion that the blilder should be drained promptly suprapubically by preference though a retention catheter in the urethra has served the same purpose in many cases. Suture of the tear i often unnecessary when the bladder i efficiently drained. On the other hand in the manage ment of the bone fragments no such definite plan has been employed but mo t cases have been disposed of simply by applying a tight bandage about the hips Direct treatment of the fragments by suture wiring etc. has been practiced on a few occasions but found unsatisfactors in the presence of urine and infection at the seat of fracture. Indirect fixation of the pelvic bone frigments by means of percutaneous screw and external clamps at points distant from the fracture extravasated urine has not previously been described. The usefulness of this method is hown by the following report

A boy to years old was brought to the hospital thriteen hour after the acident. While leading a olt with a long rope the colt broke away and ran dragging the boy about four hundred feet by the rope which had become entangled about the boy a right leg. The boy got up and stumbled along for several hundred feet before he fell unconscious He had no recollection lat rof having walked or of anything that had happened after the hore made the hirst few jumps. It was noticed that unne and blood escaped profusely through a perneal wound. Since regaining consciousness some two or three hours later he had had a constant severe pain chelly to the sacral region.

JAN M Ass # 4 box p 4

On examination he was found to suffer from shock and loss of blood seemed conscious, and complained of extreme pain in the pelvis. The left scapula was fractured transversely. There was wide separation of the symphysis publs and the entire left or innominatum could be moved bout freely upon the sacrum. A lacerated wound in the perineum two inches long and located to the left of raphé had torn through the anal mucous membrane, subjecter and and muscle wall of ectum upward for an inch. This wound extended around the urethra to the left and opened into large cavity bounded in front by the separated pubic bone fragments and the rectl muscles above and behind by peritoneum stripped loose from the abdominal wall and limited below by the collapsed bladder which was torn loose from its pubic atta himent and one-half inch curved faceration encircled twothirds of the neck of the bladder on the left sade. I ray plates showed that outside of the separation of the symphysis and marked separation of the left sacro-fliac joint there was on further fracture of

the pelvic bones. A few hours later after recovery from shock. operation was performed. The bladder wound was sutured with one row of eight interrupted chromic catgut autures. Three similar sutures closed the subjecter and rectal wall. The perines! wound was partly closed a rubber drain placed in fro t of the bladder and a permanent catheter through the urethra. The separation of the pubic bones was so marked and the fragments were so extremely movable that it was evident that some fixation of the bony pelvis was necessary. An attempt at tight strapping bout the hips had been found inefficient t hold the symphysis together and t control the excruciating pain in the sacro iliac region. The expedient of external fixation of the fragments by means of Freeman a screws and clamp was then adopted. A small incision was made on each side of the symphysis through healthy tassies, down to the bodies of the puber bones, and the screws inserted. The bones were approximated and the external clamp applied.

The pain in the back subsided rapidly after the on first from The perineal wound however was infected from the beginning, the bowels having moved involuntarily body before and after the option. All urine came through the urrelang contains all urine came through the urrelang contains and filled with modile bacteria. The linear all conditions improved steadily and the wound leaded with surprising rapidity. Daily access add irrigations of the bladder were complored to prevent increastations. On the eighth day a urinary leakage through the perineum presented. This increased in amount until the fifteenth day when the cathleter was perminently withdrawn from the urethra. Natural urination began it once and increased in volum so that at the end of the first month there was but a slight perineal leakage. A small fistula through which a little urine discharged every five very five

or six days, persisted for several months, but finally healed entirely

The Freeman screws in the public bones loosened and were removed on the twelfth day and a sacroliac belt applied. Bony union was not expected in the presence of infection b t the bones were held in fair approximation while a firm and serviceable fibrous union was extablished.

The patient left the bospital after nine weeks treatment. His orne was still purulent and a slight perineal fast is was present but he was able to walk and had partial control which enabled him to hold his urt of a shour riwo at a time.

A recent letter, two years after the accident states that be occasionally has partial urbany incontinence while 1 the erect position but be has perfect continence during the entire rught, is free from pain has pulsaance, and is good general beatth. He belongs to the class which has ecovered, although h is not f lby cured The tendency to incontinence a undoubtedly du terraction in the occurry at the bi duler neck which interferes with the sphantern functions who he is standing

The writer has conducted what is believed to be a fairly complete search of the literature and collected 126 cases of rupture of the bladder associated with fracture of the pelvis, a synopsis of which is submitted herewith. In the majority of these cases it was found that a spicule of bone had perforated the bladder. Most lacerations thus caused were extrapentoneal and several were multiple. With the exception of the instances where a foreign body had entered the pelvis from without (gunshot etc.) only four cases in which a lacerated bladder communicated with the outside have previously been described.

The treatment of the fracture itself is mentioned in only a few of the reported cases. With two or three evceptions it has evidently been limited to the application of a bandage around the pelvis after possibly some readjustment of the fragments. The treatment has often been seriously complicated by infection and necross of the bone.

Of the 137 cases now reported 34 recovered, making a total mortality of 74 per cent. But of these were 83 cases reported before 1890 with a mortality of 72 or 86.7 per cent. Of 44 cases ance 1890 e. during the period of aseptic surgery 23 lived—a mortality of less than 48 per cent. As a further proof of the increasing efficiency of

scientific surgical treatment in this clas of injuries we may note that out of a cases reported since 100 only 8 died reducing the mortality to 38 per cent No doubt this figure may be discounted to some extent by an increasing tendency to report only successful cases. The earlier reports were largely from autopsy protocol

The total mortality in all varieties of blad fer ruptures which have been treated surgically since 1000 is less than per cent. This shows in figures the extreme gravity of the lesions under discu ion and indicates that tracture of the pelvis i the most serious

complication of a runtured blad ler-

There is no reliable method of learning the facts about post-operative invalidi m in these ca es but it i to be hoped that with the en eral advance in urgical technique the ratio of improvement in result in the recovered patient may become equal to the imprive ment in mortality

PELVIC VARICOCELE

B J ALVARADO WALL, M D S TIAGO, CHILL Late Assessed Surgeon, Woman Houselal

S the Chilean literature on the subject of pelvic varicocele is scarce. I thought it might be of some interest to report. with a few comments the clinical histories of the cases I have observed

There are two varieties of ovarian vari cocele primary and secondary. The former is not associated with other genital diseases while the latter is the result of a growth or of a nathological process in the pelvic organs the ovary uterus, or broad ligament.

A condition of paramount importance in all varicose diseases, such as hæmorrhords varices, etc is chronic inflammation of the vein-wall the starting point of stasis there fore a microscopic examination is necessary before varicocele can be definitely diagnosed as it sometimes happens that instead of vari cocele we have simply a venous dilatation It is well known that during pregnancy the tubo-ovarian veins reach an enormous size a fact which I had the opportunity of prov ing to my satisfaction in a patient upon whom I operated in September 1914 for a carcinoma of the uterus. The operation was performed during puerperal involution and we were considerably handicapped in the Werthelm panhysterectomy because of the enormous size of the vessels of the uterus and broad ligament.

The same anatomical grounds in the male explain the greater frequency of varicocele on the left side the position of the spermatic vessels behind the fleopelvic colon and the

angst mosts to the renal velo should be considered especially the first factor when arera vated by chronic intestinal stasis so common among such patients. These mechanical elements are not however pathogenic we have to take into consideration the condition of chronic inflammation of the fibrous tissue which English authors call fibrosis or fibrositis and which is usually produced by a slight infecti n (Adami)

It is not unusual for these women to present a persistent cedema of the ovary and sometim's of the uterus such as the elephantiasis of a varicose leg or the enlargement of a testicle below a varicocele After a variable length of time this engorgement may end in sclerosis and finally in atrophy

A number of gynecologists call attention to the relation between varicocele and fibrocystic ovaritis. It is interesting to note the peculiar softness of the ovary and uterus when we are fortunate enough to trent the disease in a very early state before the fibrot ic processes have taken place and gained some ground. The uterus is very soft, like an old cloth, and its walls are compressible. Such characteristics are not found in other conditions which are accompanied by utenne swelling with perhaps the single exception of a uterus shortly after a miscarnage.

The symptoms are very unusual patients, often multipara complain of pain in the lumbar region and in the lowest parts of the abdomen. The pains are aggravated when the patient stand and during or near the menstrual period and they abside when the patient lies down or when the flow ha started As the physial ign are very poor and often quite negitive these pior patients are relegated to the large group of so-called neurotic The men care about dant and irregular at to duration and date of beginning Another symptom often men tioned in the clinical hi times of pelvic vari cocele i the waters leu arrheea which i very difficult and tediou to treat and like the other symptoms 1 greatly agenivated during menstrual periods

The physical examination is very often negative but in favorable cases we feel a hard lump ituated below the overy which i almost always swollen and flaccid at the bottom at the pouch of Douglas When standing the palpation will be more positive and when suspected we must have recourse to examination in this position

The co-existence of varience veins in the lower leg and labia will be of assistance in the differential diagnosis

The diagnous after all we have said may be considered difficult and usually made by exclusion as is the case in all diseases which are accompanied by a few phy ical igns

If a patient complains of pains which are made more severe by standing or walking and which are ameliorated when lying down if these pains increase when the menstrual flow approaches and when the men es are very profuse then we have sufficient reason to suspect a varicocele more especially when palpation reveals a soft mas quite independ ent of the ovary and tube. If the penneum is flail not resistant and at the same time varices and a blui h color are to be seen on the collum uters and vagina the diagnosis is fairly sate

Chronic appendicates is the commonest error made in diagnosing these cases. Some of these patients are subjected to appended tomy with of course negative results. Chron. ic metritis is the next most common error Thi is very easy to explain it we remember that leucorrhora and an increase in the size of the uterus are two of the most frequent to venou state and the tranudation of lymph is the cau c of these condition hu orthicall very peculiar in these cases and it we a k the patient in re closely re pardin it they alway tate that the fluid i waters like urine quite litterent from the vellow di charge in a e i metriti

Some urgeon are of the punion that tibrocystic oxanti a aten the result of pelvic variescele other deny any relation ship between these two diseases. Without enfering into a di un non nothini int I think the practical c n lu ion to le frawn thereign i that not we have made the brtdiam i we are in n will lith rized to deny the exitence of the latter but on the contrary our duty in such a large to investi cate it

With these incomplete mment and be fore ging into particular a to treatment let u briefly summariae the complication or anəmalər symptəm

There are in the medical literature some cases of retro utering hamat well and marian hæm rrhage which po ibly may be attribu ted to rupture of a varies even. The bur t ing and bleeding may take place between the layer of the broad ligament thu giving rise to a hamatoma the result of which is ultimately and usually a fibrou new gr wth a kind of tibroma

In October 1914 I operated on a woman suffering from a uterine cancer and as I found in the vicinity of the uterus a lump the size of a hazelnut I feared it might be of the same nature and the operation useles tum it was situated below the right overv and its surface gave the appearance of worm The pathologist's report ay fibroma fortunately there were no further detail

As during pregnancy the varicose veins un dergo a greater development it i not unlikely that profuse hæmorrhages may upervene and the treatment of this condition is sometimes very difficult At the annual meeting of the American Medical Association held at Atlan tic City in 1914 Zinke of Cincinnati gave the history of a woman 35 years old ix weeks pregnant, who consulted him because of profuse himorrhage. He curetted her The bleeding however continued during five

months, at the end of which time and know ing that she was again pregnant, he resorted to laparotomy. He found a soft mass which he believed to be para ovarian and which he removed. The patient recovered her pregnancy following uninterruptedly its normal course.

The treatment should only be surgent if we aim to obtain a permanent cure. Miedical ly we can relieve the condition of such patients if we advise the recumbent position and the correction of pelvic organs by means of a vaginal plug or a reconstructive perineal operation

R. G age #8 III-para two miscar riages, the last one a year before Since then m natruations were very profuse and painful. She complains f paus in both loins and deeply in the hypogastrium. She feels tiresome sensation. At the beginning of June th pains became more mark ed and she vomited several times. She had an abundant serous leucorrhora which she could differentiate from that of some of her relatives who suffered from chronic metritis. The portio vaginalis was enlarged, the copus voluminous and soft. Behind and to the left in the deepest part of Douglas pouch, a ound, even and soft mass is easily palpuble and tender t pressure. It wa believed by myself and other examining physicians t be acherocyatic ovary

Median laparotony June 36 10 6 The left The utero ovarian vensels were greatly distensed. The left ovary and accompanying the were moved of great portion of tubo-ovarian vens by means of an inculon of broad ligament parallel t the round ligament were resected

Once the varicoccle was recognized w immediate ly inspected the opposit sid and as we found it the scat of a beginning stass we decided to pass two or three ligatures through its most conspicuous veins.

The uterus was enlarged, reddish blu in color and so soft that it could be modded between the fingers, condition not previously observed by us. The removed overly was cut along its median line, giving a splended view of the engoged veins.

Microscopical examination showed a varicocele and orderna of the overy The removal of this organ

was, as is demonstrated, not justified.

CAST E. D., p. 24 multipars. As a result of violent train five years are she felt an intense pain on both sides of the lumbar region. The pain, though less severe has persisted since that time. The periods are irregular and painful. She complains of poin on the left side of the hypogastrium. The pain is more marked when mensitual flow approaches.

The light kidney is alightly mobile the uterus is small, a little troverted and movable the left appendage is cularged and tender to pressure. A diagnosis of retroversion of the uterus and left adhesitis was made. Operation August 20 The left overage and tube were absolutely ormal. The to-ovarian venous v seeks on the left side were more diluted than usual. The right ovary was mileron tie. The views we very large private the broad lignment rather striking blutts color the broad lignment rather striking blutts color the broad lignment. The right of the broad lignment rather striking blutts color pendis removed, and both round lignments were shortened (Dolfar Richelot).

It is interesting to note the co existence of sclerocystic ovantis and varicocele. I think it is very likely that the former is the end result of a prolonged stasis. I do not claim to prove that such is the only cause of this engmatic ovarian disease my object is to explain the relationship if any between the diseases.

The surgeon may and upon opening the abdomen that no veins appear and he may thus fear a mistake in diagnosis has been made but the explanation is very easy as the Trendelenburg position favors venous circu lation the pelvic veins, following the general rule empty with incredible rapidity and everything appears normal. In the patient whose history I have just given and in the next one I could conclusively demonstrate this phenomenon This is. I think the cause of mistake in a patient where the palpating hand very distinctly discovered besides the ovary and tube many soft and elongated masses which disappeared after prolonged pressure. I was justified in making a tenta tive diagnosis of pelvic varicocele and fibrocystic ovary The operation did not confirm the pre-operative diagnosis.

CARE 3 M. A. C. ago 38 \ para menses of four days d ration until that time since then they are regular and last week. The portio veginalis is large and hard the corpus is enlarged. The uterine probe induces bleeding. The right ovary is easily parjected, is the size of a peanut, and is soft, fluctuating and not tender to presum.

Diagnosis cyst of right ovary chronic metrifit. The laparotomy was performed under spinal analysis (Jonesco) and the diagnosis verified A varieccele of the same side was also discovered. The veins were enormously dilated and they completely collapsed as soon as the supine pealtion was assumed.

W opened the layers of the broad ligament and

resected a few centimeters of the most prominent veins. The ovary was the sait of a strous cyst and covering the surface of the tube, there were numerous small cysts both ovars and tube were removed. The appendix was removed. The left broad ligament and appendage were normal

From all we have said the conclusion to be drawn is that this disease is not so rare as is usually thought and as would be indicated in the papers written on the subject. It has

been regarded as an exceptional condition because we do not expect to find it and be cause even when diagnosed we sometimes tul to recognize it as happened to me

PURPURA HÆMORRHAGICA FOLLOWING MENORRHŒA

B TRANCIS ROL BENHAM M.D. S RACL I

N presenting a paper on the subject of purpura hamorrhagica tollowing menor rheat it is not the purpose of the writer to discus or pectulate on the euology of this condition. However the cause of the condition is and has been a matter of a great deal of theorizing and experimentation and I will therefore give a few of the theories advanced.

Briefly purpura hemorrhagica may be defined as an abnormal condition of the blood or blood vessel and possibly both character ized by the appearance of hæmorrhages in different parts of the body. These hæmor rhages may be subcuticular submucous or subserous in fact they may appear in any The subcuticular varieties part of the body appear under the skin and vary in size from a small pin point (petechiæ) to the large ec chymotic patch The submucous is found as the name implies under the mucous mem branes Its size and appearance is not unlike the subcuticular The subscrous are found under the serous membranes.

The case which I shall report had all these different varieties of purpure hemorrhages

There are many theories and opinions expressed as to the causation of this malady. Certain infectious diseases such as typhoid and malaria seem to produce a condition of the blood that not intrequently leads to at tacks of purpura hemorrhaguea.

Letzerick believes purpura hæmorrhagica to be of infectious origin and has isolated a bacillus not unlike the bacillus of anthrux Auto-intoxication 1 said by others to be a causative factor in the production of this disease. It is thought that certain toxins absorbed from the intestinal tract so act upon the blood or blood vessel or both that coagulation is interfered with and as a result we have the himorrhagic diathesis with productin of purpura

Silbermann believes that in these cases blood pressure in the capillaries is greatly increased and as a result some of the small capillaries may rupture and thus throw blood into tissues. A gain it is said to be produced by a process of diapodesis.

Kogerer and Silbermann who have spent much time in the study and experimentation of this condition summarize their work as follows. First the condition is the result of vascular disease. Second as a result of the vascular disease there is thrombosis formation. Third following the thrombosis there is extravasation of blood. Fourth following extravasation there is a discoloration of tissues and pigmentation.

The many and varied opinions expressed show that the etiology is unknown. I have very briefly gone over some of the literature on this subject to show the wide variance of opinion concerning the cause.

Inasmuch as we do not know the cause of this disease we are compelled to treat the condition. I believe the blood-count to be the first and most important initial step to be undertaken in the treatment because if this condition is produced by a lack of cer tain elements of the blood these may be artificially supplied. This technique proved to be of great benefit to me in the particular case which I report.

I wish here to indorse the blood transfusion method as given by Richard Lewisohn in the American Journal of Surgery under date of October 1015 By this method the entire blood is injected direct from donor to recipient. A cannula is inserted into the vein and a 20 ccm, syringe filled direct from donor and injected direct into recipient. As large a quantity as is desired may be injected. The technique is the simplest of any blood transfusion operation I know of It is not however without danger to the recipient. If too much blood is injected or it is injected too rapidly acute dilatation of the right heart may result. There is also danger of injecting too much air. A small quantity of air can be taken care of but a large quantity is extremely dangerous.

Purpura hemorrhagica is found most fre quently in women

In reporting my case I wish to emphasize the importance of family history as not infrequently we discover other members of the family to have been likewise afflicted

A woman, age 34 father 65 and in good health mother died at the age of 54 of cerebral hemorrhage, two brothers and three saters are living and in good

As far as I am able to learn none of the ancest rava erre affected with this disease. When the patient was y abe noticed few spots on her shina. These were at that time disposed as ring worms these circinata. She has two children six and nine years of age. Both confinements, hard forceps deliveries. Was increated both times but reparred, hever has had by miscarriages. She began to measurant at themsel both mines but reparred, here has a state of the second that the second began to measurant at themsel bound as to time and quantity until about two years after the borth of the second child then she noticed flowing was excessive and it lasted six or seven they.

Purpuric spots would appen on different portions of her body last a few days, and then disappen She did not consult a doctor u til 9 3 when she moved to Syracuse and consulted me regarding fallen arches. At this time no mention was made of any purpurs posts or mentirual trouble. F brunry ore she had eart pendiddis. I removed large scrutcy infamed appendix which was glued t the

top to the fleum. Recovery was rapid and she returned home from the Homeopathic Hospital in two weeks. During or following the operation no trouble was experienced from hemorrhage, neither did any purports spots press

Seytember of 1.1 was again called because of memorrhors. Th menase had at that time lasted eight days and the flowing was increasing in tend of bating I was at first maybelous I miscarriage or if not that uterin polypus o fibroid. History and examinations revealed thing and I was at a loss to account for the count of the wing. Doctor W. A Groat was called to mak a blood count and examination which was Red blood-cells, occ, occoorgination decidedity etarded hismoglobin 40 per cent leterocytes, 6 occ.

There was protound accordary anemia with great red ctoos of blood platelets. Ergot and pitultim had been gi en t assist in controlling hemorrhage with no effect. With the knowledge that the vagulating power of the blood was so greatly educed borse serious was injected to come every day for the weeks. Micra a few days the flowing begant decrease in quant ty. Menstrua then he were co t used from o e period into an other and finally stopped cuttrely before the third period. The diministration of horse serum hypoder mut cally was co tinued bet re and during the cutting the control of the serious control of the control

D in g th entire neckness, purposite spots would prea in different parts of her body these spots varying in size and appearance. They would pear generally in ever following mensituation. At first the spots would be the small petechie found actitered over her need, of arms. These would hast several days then the large exchymotic patch ould appear in different parts. There seemed

to be no partial underent pairs have seemed to be no partial place where they would appear. These would last like any black and blue spot and then gradually fade any. The partients shalts of life were regulated, and proper hypicale instructions were given beaseds, general took treatment and the hypodermic use of froe dirate, etc. There was great improvement in the general condition. She ould go and do as she pleased and enjoyed life in general.

Åpril 8 0 5 the menues poesred as usual but the flowing was greatly increased. Vaginal exammatio revealed an erosi n on the scar of the former laceration from which the blood was streaming Local treatment was fundituted to stop the hemorrisage. Silver infrate 5 per cent solution was applied followed by packing with games asturated in ... ooo adrenalin sol tion. The horne serum was injected every day still I could see no alleviation of the symptoms.

Doctor Groat at this time made another blood examination as follows Pale hemoglobin 30 per cent erythrocytes 600,000 congulation decidedly retarded color index o 8 leucocytes 5,400 secondsty anomia. The comparison of the last blood out with the first shows the same serious secondary mamua but to a much greater degree. It also reveals I the fact that she was nearly examputing the Her skin was as white as the heets of her bed the mucous membranes of her mouth and lips y in white as her skin. The case now assumed yin all rining proportions. She was in a condition of hock most of the time head I reath hung in then he would feel faint. Her body and face were covir d with old persporation.

At the suggestion of Dr Meader coagul se was tried still the flowing ontinued. She was lit rally At the tage ight oun is f bleeding to d ath human blood was obtained from her husband and injected. This seemed to modify the scrious symptoms a great leal The fl wing continued irr spec tive of treatment. Operative interfer nce was ad vised against still I could see the ontinual ham r rhage coming from the cross n on the ervix Operation was decided upon and the utemne arteries were tied off tollowed by "urettement. The hamor rhage was rather sev re but after the application of pure carbolic and f llowed immediat ly with application of alon 1 the uterus facked with gauze saturated in a solution of adrenalin 1 1000 the homor rhace ceased. The operation was very will borne

Human blood scrum was injected as oft n as I could obtain same from husban! Scrumpings of uterus were sent to Professor's tensland of Syracuse Medical College for pathological examination as I felt possibly mal grancy might have some learing on the case. Professor Steensland reported the

condition innocent

Following this operation which vas performed at the patient's hom purpoint spots covered her whole body and lined the mucous membrane of her mouth nose and throat also many hemorrhagic spots appeared in the vagina. During this time she had frequent nose bleeds which were very difficult to control also if she would brush her teeth expecially hard so as to erode a small particle around a tooth this would bleed perhaps twelve or twenty four hours.

The cervix presented such a large stellate lacera tion that in my opinion it would very soon undergo degenerative changes and I considered this to be one of the chief causes of the menorrhea

I decided to amputate as soon as the condition of the patient warranted.

June 16 patient was removed to the Homocoppathic Hospital and on June 1 I amputated the cervix. Convalescence was uninterrupted and she returned home in two weeks. The menses appeared every twenty-eight days at first and were rather prolong I and excessive lasting about ten day. The condition has materially improved until now the entire Iteration is his days. One week following the exsation of menses small petechne appear on different part of hir body. There is no pain or tendemess no symptom of feeling week and no in oncinence faink in I file espot last a few day, and then disappear.

She has gained in vight weighing 140 pounds and look the picture of health. This affect ogo and do a he hoose. Examinations of the blood till how slight anamia with some refuction of

blood platel t

Purpure pots also appear a they have before but the quantity; much small r. The treatment now on ists of proper hygiene and intravenous use of iron

I have every reason to blieve that this ase will entirely recover improvement has been so great

and is steadily progre ing

To summarize The laceration of the cer vix in the case produced a subinvolution of the uteru thu predisposing to increased and prolonged flowing and reducing the quality and quantity of the blood as a whole The condition lasting over several years produced vascular disease. The vascular change seemed to have affected the power of the blood to coagulate at the proper time Blood examination show that it is the lack of blood platelets that produce the condition vascular disease is given by some writers as the first and primary cause of the disease Constituents of the blood were taken away from time to time faster than the forming elements could supply them Resulting from this we have a slowing of the blood stream and finally stasis with the formation of thrombosis and pigmentation

The appearance of the petechie and ecchimotic patches following menstruation show that at that time the coagulation power of the blood is at its lowest point consequently. I believe the treatment at this particular time should be to supply if possible the los of blood by the direct transitission method namely the method of Richard Lewichn alluded to in the early part of this paper.

THE RELATION OF THE ENDOMETRIUM AND OVARY TO HÆMORRHAGE FROM MYOMATOUS UTERI¹

BY SAMUEL H. GEIST M.D. NEW YORK From the Pathelogical Laboratory of the Mount Small Reports.

THE commonest and perhaps the most important symptom associated with uterine fibromyomata is undoubtedly harmorrhage either in the form of menorrhagia or metrorrhagia. It has been the aim of many investigators to arrive at some definite explanation to account for this hamorrhage but as yet no conclusive evidence in support of the various theories has been advanced. Hyperplastic changes in the endometrum have been noted as a common occurrence associated with bleeding and fibroids and consequently these conditions have been correlated by some authors. Others have attempted to link the homor rhage with inflammatory changes either in the endometrium or in the wall of the uterus. As would seem natural, because of the size and situation of these tumors mechanical causes, as pressure or obstruction with dila tation of the vessels, have been assigned an important rôle in the etiology of the hæmor rhage. One important organ, however has been neglected, but in the light of recent contributions to the physiology of menstrua tion and of the demonstration of amenorrhora produced by the \ ray in treating fibroids and other conditions, the definite part played by the ovaries in the causation of hæmorrhage must be emphasized

A brief review of the more important literature illustrates the various theories that have been advanced and shows how little attention has been directed to the study of the ovary as a possible etiological factor

Von Campe (1) studied forten cases of intromyomata, and found hypertrophy of the endometrium which he believed to be due to the presence of the tumor Wider (2) in an examination of twenty cases of fibromyomata noted the frequency of the endometrial hyper trophy and believing it to be inflammatory called it endometritis glandularis. He believed that this change in the mucosa had no relation to the hiemorrhage. He found

in those cases in which there was a concomitant harmorrhage that an interstital inflainmation was present and suggested that the inflainmatory condition was the cause of the harmorrhage as well as the cause of the hypertrophy of the mucosa. His pictures, however do not show a true interstital inflammation.

In the cases investigated by Uier (3) the same hypertrophy of the mucosa was noted and for the first time was considered apart from the tumor proper. The idea was advanced that some external irritation the same that in the musculature causes a circumscribed connective tissue overgrowth, produces an overgrowth of the mucous membrane.

However to disprove that the tumor produced the endometrial overgrowth, Cornil (4) demonstrated that the hypertrophic change was more commonly associated with small than with large myomata.

In an attempt to ascertain if the situation of the tumor had any effect on the mucosa, Schmal (5) analyzed fifteen cases and found that in subserous tumors the mucous membrane may be normal or hypertrophied while in the interstitual and submucous ones the endometrium over the tumor usually is atrophic elsewhere it is hypertrophic.

Semb (6) from a careful examination of fibroid tumors considering especially their situation the type of mucosa and the amount of hemorrhage concludes that the commonest change in the mucosa associated with fibromyumata is hyperplasia. There may however be changes of a secondary nature such as inflammation or atrophy from pressure. He believes also that the hypertrophy of the uttrile walls and vessels and the pressure of the tumor on the veins may cause the hemorrhage.

With the work of Hitschman and Adler (11) on the cyclical changes in the mucosa, it was necessary to study the effect of the

tumor formation on the normal mensional cycle Frankl (1) was the first to investigate the endometrial changes in myomatou, uteri in relation to the normal men trual pha e-In the subserous and pure inter titual types of tumor he found that there were no changes in the endometrium that could not be included in the normal men trual rhythm. In only one case was there a hypert la 1a of the mucosa with rather marked ordens which latter condition was believed to be due to mechan ical interference with the circulation interstitial tumor, with a tendency to grow toward the cross how no abnormal variation in the cycle and th se or wing toward the mucosa lilewise don t di turb the normal phases. In numerou in tance he f und a moderate thickening of the mu sa due to ædema and in other in tances where the tumor projected into the utempe cavity, he found pres are atrithy tithe end metrium

Clirk 8 examined a number of fibr m at u ut ri and tudied especially the circular ry apparatus by means of injection experiment. He ame to the conclusion that the ituation of the tumor and it consequent mechanical interference with the circulation was the main factor in causing the atypical hamorrhage.

An analy L of the foregoing work shows how at variance the different theorie are Mo t of the investigator however have found that the mucosal often hypertrophic sime attaching to the an enological signin cance in relation to the himmorphage while others imply regard the hypertrophy as a councidental infilm.

While you Campe (1) believed that the hypertriphy wis due to the presence of the tumor Cormil (4) was able to show that the size of the tumor had nothing to do with the hypertrophy and that the larger the tumor the less likely was one to find a hypertrophic mucosa. This seems to throw considerable doubt on the theory of you Campe.

Frankl's contention that the thickening of the mucosa is due to addem is not borne out by histological examination microscopically one can see not only addems and conjection but hyperplasia and hypertrophy of both the glandular elements and the cellular constit

uents of the stroma. The conclusions of Clark that the hæmorrhage i due to a me chanical condition will be discussed later but we believe that this theory of mechanical obstruction is not the entire solution or even the most unportant factor.

In an attempt to correlate these various theories especially in the light of recent contributions to the phy iology of menstruation and its relation to corpus luteum evolution I studied seventy hive informyomatous uten representing all types of tumors and presenting various symptoms. In all the cales the menstrual history was accurately investigated In sixty cales the addiexa were also examined of the seventy hive cases fifty gave a history or menorrhagia some few also having metrorrhagia.

It we analyze the histological changes in these fifty cases we find that in thirty six or 7 per cent the mucous membrane of the uterus showed hypertrophy irrespective of the phase of the normal mensional cycle. In one case the mucosa was not examined but an adenomatous polyp was present the glandular elements of which had the same charac

teristics as those to be described as typical of the hypertrophic endometrial condition.

In three instances there was an atrophy of the mucosa associated with large tumors, due in all probability to pressure, and in ten matances the endometrium was in the resting or interval stage though in two of these it approached the hypertrophic picture. In other words the most common condition found in the mucosa in the bleeding cases is an hypertrophy

A closer investigation of those cases that had abnormal bleeding and did not show the typical picture in the mucosa, is instructive. Of the thirteen cases that showed abnormal bleeding and did not present the usual hy pertrophic mucosa, five showed a condition of alight hypertrophy and ordena with some tortuosity and dilatation of the glands in other words a mild attempt at the usual picture Three cases had atrophic mucosa associated with large tumors. The atrophy however occurred over the tumors and on the uterine wall opposite them, where the question of pressure undoubtedly played a prominent part, while the mucosa between the tumors showed decided hypertrophy Five cases presented the typical interval or resting mucosa. In these five cases we have no explanation to offer for the absence of the hypertrophy An analysis of Table I will show how absolutely independent the mucosal change is of the attraction of the tumor and also of its size

Of the twenty five cases in which the

menstrual history was normal Table II illustrates the relation between the situation of the tumor the menstrual cycle and the condition of the mucosa

In this group of cases we have but nine or 6 per cent that presented the hypertrophic change and fourteen or 36 per cent showing an interval stage. In two cases no examina tion was made of the mucosa there being present in these instances adenomatous polyps Of the nine cases with normal men strual histories in which the mucosa was hypertrophic one was menstruating on ad mission. Seven were operated upon at the time of the normal premenstruum. One an patient of 40 had amenorrheca for four months. Of this group only the last case cannot be explained as due to physiological causes.

In other words arrespective of the size and situation of the tumor in those cases giving a history of metrorrhagia or menorrhagia and irrespective of the phase of the menstrual cycle we and a markedly hypertrophic mucosa. It is not ordema alone for all the elements of the endometrium take part in the change. The glands are tortuous distended often cystic and sometimes increased in number The cells lining them are large with pale staining protoplasm and contain basal or centrally placed nuclei dark stain ing and oval in shape The cell border toward the gland lumen is often raised in the form of a little cap or knob which is granular and when stained by selective dyes shows the same tinctorial characteristics as the secretion which is almost always found in the gland lumen

The cells of the stroma are somewhat en larged and pale the nucleus small round or oval deeply staining and centrally placed. Where there is much interstitial cedema the cells are separated for a fair distance but in the absence of ordema the cell bodies are barely distinguishable and the cells closely crowded together. There are no evidences of inflam matory reaction as a rule, though occasionally one may find inflammatory cells. Blood extravasations are found though not often These are situated under the mucosa or in the interstitial tissue.

rmal premen trual hypertrophy

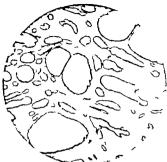

The entire histological picture resembles ever much the changes one find in the muco-aliuring its normal premen trual phase and it seem rea-onable to suppose that the same stimulu namely some overnan activity is the cause of the hypertrophy found associated with fibroid. In the uten from the cases of essential uternie hæmorrhage (Geist 10) we find a similar hypertrophy of the mucosa and this type of hæmorrhage is now generally conceded to be due to a disturbance of the balance of the endocranous glands.

In an effort to ascertain if there were any definite lesion in the ovaries the ovaries in thits the cases were also carefully examined. In thirty-cight there was a history of bleeding and in seventeen the menstrual history was normal.

TABLE IV B

Condition of ovaries in 8 patients with normal menstrual history and no hypertrophy With normal ovary With cysis

microcyst, dermoid With inflammation of tube and on r

In considering the adnexal changes in relation to the bleeding and to the changes in the mucosa we are struck by the predom inance of one type of lesson in the ovary namely the perastence of a large corpus luteum which is occasionally cystic. In sixteen cases or surty two per cent of the twenty-six with hypertrophy of the endometrium we found this condition of perastent corpus luteum and only in three instances were the overles to be classified as absolutely

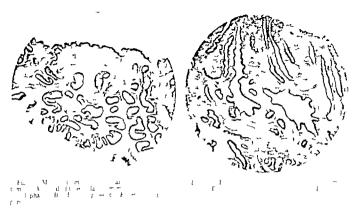

lig 4 Mis wa from terms intaining submiscons fibroid \ px_id glands ministing the premenstroal phase Last period one cell ago

normal In the nine cases in which the mucosa was in the resting stage only two showed this ovarian change and in one of them there was a slight hypertrophy of the endometrium

Of the seventeen cases in which the men strual history was normal only two showed the large corpora lutes and in these there was a premenstrual change in the mucosa

An analysis of the foregoing cases shows that when the mucosa is hypertrophic and pathological bleeding is present the ovary is grossly abnormal presenting either cysts, inflammation or most commonly a large corpus lateum often cystic in character

We have seen that in the majority of cases of uterane fibroids irrespective of their size or stutution, when the condition is associated with pathological bleeding the mucosa presents a hypertrophic condition resembling that seen in the normal premensurual phase of the menstrual cycle. The recent work of Ruge and Meyer (9) has shown that the normal premensurual phases correspond in time to the height of development of the corpus luteum and that the hypertrophy of the mucosa is probably duct to ovarian activity or more specifically to corpus luteum activity. We thus have reason to believe because of the resem

blan e between the two pretures it the muse that the arre timulu perhap para rt li the aux 1th hypertrohy 1the mu ain th phrid are. In most title are when atrochy was und the nitten ull be acconted a reither by ore ure ir molar e tu mr rby emitty Intw t the a-c-where there had been pres ure atr phy we round in the paces between the tumor a hypertrophic conditi n which resembled that u ually toun lin the bleeding cases. have a common or related etiological factor In further support of this theory can be ad vanced the evidence of X ray therapy is established that the \ ray treatment of bleeding fibroids quickly stops the hæmor rhage long before the size or situation of the tumor is influenced. We also know that it is the overy and more particularly the more mature follicles that are first affected by the ray and consequently feel justified in regard ing not the tumor but the ovary as the important factor in the cause of the bleeding

Supportive evidence pointing to the activity of the overy as the source of the hemorrhage, is found in the clinical behavior of fibroids associated with pregnancy hæmorrhage from fibroids during pregnancy in most instances, though the tumor in its size and situation remains unchanged ceases The ovarian activity is to a great extent in abevance during pregnancy and it seems that in view of the previous discussion we are justified in assigning the important rôle in causing the cessation of the harmorrhage to the functional inactivity of the ovary

To summarize, we can say that in most of the cases of fibroid uterl associated with path ological bleeding we have a hypertrophic condition of the mucosa. The ovaries in these cases vary from the normal, there being present most often a large corpus luteum occasionally cystic. These findings seem to us very significant in view of the fact that the ovarian influence is of primal importance in regulating the normal harmorrhage from the uterus and it seems reasonable to sug gest as a possible etiological factor for the atypical hemorrhage associated with fibroids, il turbance in the function of the overs perhaps of the corpus luteum

I wish to thank Dr F S Mandlebanm director of the laboratory for the privilege of studying the material and for the excellent photomicrographs which he made and also to express my appreciation to Dr. I Bret tauer and Dr F Krug for their kindness in allowing me the use of the clinical data.

(The photographs illustrate variations, from the normal picture as seen in the uterine endometrium associated with fibromyomata. The varieties pictured represent types of hypertrophies where one would normally expect a resting stage.)

SARCOMA OF THE SCAPULA HISTOLOGICAL DIAGNOSIS MADE BY STUDY OF BLOOD ASPIRATED FROM PULSATING PORTION OF THE TUMOR

BY C E ROLLE AB MD ION CITY ION Department of Pathology and Bacteriology Rate University of Long

THF cytological study of the various exudates is a well recognized labora tory procedure and has a proved value in distinguishing between neoplasms and various types of imflammatory processes affecting the linings of the serous cavities. That a similar study of fluids aspirated from tumor masses may have a like value seems possible from the instance I shall relate

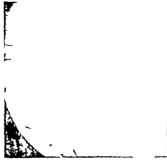

Among the specimens coming to the labora tory recently was ten culuc centimeters of The accompanying request fluid blood card stated that the fluid had been aspirated

Fg 1 Photscraph showing timer of night hould

from a tumor of the houlder which was tentatively diagnosed as sarroma and asked for the nature of the fluid. The fluid was all well to tand over night at from temperature. The next morning it was clotted. Ten per cent formalin wa, added without disturbing the clot. The following day a portion of the clot was removed and imbedded in parallin. Sections from the block stained with hæmatexlin and eo in present beautiful pictures of island of sarroma-cells imbedded in a matrix of ubrin and red cells. The cells are of the small round variety and mitotic figures are frequently seen.

The history shows the patient to be a white male 19 years of age single of good habits and without previous illness. The family history 1 irrelevint except for the vague titement that hi mother died of a tumor of the temach. He complains of pain and swelling of the right houlder. The duration of

|F|g|=R Sentgenogram, howing cavit, it rination with in the turner

the tumor covers four years and date to an injury of the houlder while coasting. The growth has been slow but there has always been more or less pain.

UNILATERAL HÆMATURIA ASSOCIATED WITH FIBROSIS AND MUL-TIPLE MICROSCOPIC CALCIUL OF THE RENAL PAPILLÆ

B R L PAYNL I MID FACS N RPOLL V RGIN

URING the past decade there have been many articles written on unilateral hermaturia and like all other unsolved pathological problems, there have been quite a diversity of opinions expressed.

At the meeting of this society in 1912 the writer presented a paper setting forth a fesum? of the vanous pathological inter pretations published up to that date and related a series of experiments which belped to eliminate the acutely developing vascular lesions as a causative factor of unilateral renal homorrhage.

A large number of careful observers have reported the evidences of chronic inflamma iton in sections of kidney tissue removed from the type of case under consideration and our studies of personal cases before and since 1912 have confirmed the belief that chronic

Serg Oyeet & Obst 3 rv11, 41

inflammators changes are the principal factor in the production of unilateral hamaturia.

We also advanced the theory in the paper above mentioned that chronic inflammatory changes raise the local vascular tension to the point where rupture of the capillaries occurs with a resulting himorrhage

The tollowing case is presented not with the idea of drawing therefrom any definite deductions but for the purpose of explaining and defining our interpretation of the pathol ory present in this particular case

C II J male, age 7 occupation, school-teacher family past and social history egative. Present history Seven years ago he first observed the presence of blood in the urine. This occurred at varying intervals until three years ago alone which time there has been blood continuously present in the urine.

The patient has never suffered a particle of coll or pain, nor has there been associated any spells of fever. The amount if urine passed has always

been pl ntiful but the patient gives the history of peristient constipution. There had been a per ceptibl loss of neight and the patient looked very anamic. On physical examination neither kidner was palpable and there was no tenderness over eith r loin space. A ray examination was negative to stone and the microscope revealed an abundance of blood in the urine but no pus no crystals and no casts.

Casosopi examination showed a normal bla Her with Hoods urine apurting from the right ureter and clar urine from the left side. No resistance has met with either urcteral catheter but the separate specimen showed with the microscope lear urine from the left kidney and bloody urine from the right side. Functional phthalem tests showed a normal output from the left side and a mark I reduction from the right kidney. Bacteriological studies of the separate specimens was negative from the left kidney but showed a few colon bacilli from the right kidney.

Bactenological study of the bladder specimen also showed the presence of colon bacilli

Operation was decided upon because the writer has observed several of these cases relieved by section of the kidne, from pole to pole and down to the pelvis in the absence of any demonstrable lesion to the naked eye.

At operation the Lidn v seemed normal in appear

Fig. 4. Microphotograph Vi3. taken tom same section. Fig. 3. shows five calculi numerous dilated capillaries, and considerable connective tissue overgrowth.

ance and size and no stone or ne v growth could be demonstrated. Upon bisection the cortex and parenchyma showed nothing definite but every single papilla was miensely ongested and the tip of every papilla presented a cherry red appearance which concided macroscopically with the classical description of an angiorm

The writer had never before done a nephrectomy for this condition but it did not scen reasonable that bisection with nuture could releve this particular ase nor did it seem possible that the experience of Finnick' could be applied to multiple angiomata of every papilla

Haring in mind the normal functional test of the

Haring in mind the normal functional test of the left kidney nephrectomy was accordingly done and herewith is appended the pathological report by Dr Wm DeB MacNider of the University of North Carolina.

Gross appearance Kidney in 10 per cent formulin is 4t xaxit; inches. The capsule is easily removed not adherent and the surface is smooth and normal in color. The cut surface shows a normal r lation of cortex and medulit.

The cortex is unformly pale. All of th pyramids appear congested. This congestion macroscopically takes the form of treaks running in the long axis of the pyramids. In several instance, these streaks leaf to areas of ongest a red lish

Brat M J 000 10.

brown in color which surround r cap the apices of the pyramids. All of the renal papillo show marked congestion.

Hieroscopic pathology. There is no increase in intertubular connective thanks and no aderoals of the vessels. The glomeruil do not show any in crease in capsular connective thasise. There is however quite an uniform increase in connective thanks cells between the capillary loops of the glomeruil. This connective-thank change is likely of recent development because connective thanks there have not been laid down.

The capillaries in this area are intact, bence, there is no evidence of the hematuria having originated from a ruptured capillary loop or loops. The epithelium of the cortex appears normal. The tubules in the cortex occasionally contain granular

material which shows an absence of red blood-cells. Sections were made passing through the papille and pyramids both in the long axis of the pyramids and at right angles to this axis. Such sections show the crithchium of the tubules in this zone of the kidney to be fairly ormal. In the region of the papille there is a distinct increase in inter tubular connective tissue. This increase is not uniform in its distribution.

Located in the region of the papille and principally between the tubules but rarely inside a tubule are numerous calculi which are microscopic

Fig 6 Microphotograph, \ 8 of same section as Fig 5 showing the diluted and reptured capillary containing few red cells and abundant hemorrhage on the surface of the pupille

In size S rrounding and in the region of such concretions there is an unusual overgrowth of connective tissue. In this connective tissue, usually between the tubules, th. small velus and capillaries are hugely dilated int. venous sinues.

Many of the small calculi ii in close apposition to these vascular sinuses. Such sinuses e well filled with blood. In such reas the t bules may be compressed by either the dilated capillaries or th intertubular calculi

All f the papille three dilated capillarie net work on the surface many fahick wer ruptured with free blood ese pi g. These mer bi mall variees were crule if it so ree f the hemorrh ps.

The origin of these varicostites is not clear it would seem however that the numerous though small calculi aided by the connective tissue they had originated succeeded in causing an obstruction to the venous return and a subsequent dilatation of the capillaries with resulting varicosties.

The writer does not believe that deductions can be drawn from one case. The facts here presented would however lend weight to the theory of those who believe chronic

inflammation to be the cause of unilateral renal hymorrhage

Briefly to summarize we have a case of so-called exantial hierarchia which hows in the kidney removed that macroscopically the only part of the organ involved in a pathological process is the pupillary area.

Microscopicilly the cortex and medullary portion is pathologically negative while the papillae show definite lesion as follown (1) Numerou microscopi calculi (1) over growth of connective tis uc (3) hugely dilated capillaries (4) calculi lying in close apposition to dilated capillaries (4) dilated capillaries in a net work on the tree urface of papille many of which are ruptured with free blood escaping

It is not the part of this paper to discuss the question of infection harmatogenous or other wise whether the stones were the beginning of the process whether the connective-tissue overgrowth was the cause of the variousness or in any way to theorize concerning the causative factors involved but to report accurately our hidings and partly show them in the accompanying illustrations.

Finally after five verys of study of so-called essential unditeral hamituma both clinical and experimental together with an intimate knowledge of the literature this is the first in tance known to u where the definite

har Mu opbut graph \(\text{152}\) Section through up of papilla showing a lituted apillary ut in its I mg axi. It said inded with blood but ruptured on the t ee border of the papilla.

source of the hamorrhage and the probable cause thereof in a case of symptomiess unlateral renal hamorrhage is shown

THE PROCESS OF REPAIR IN WOUNDS OF THE SMALL INTESTINE

B JOHN E. McWHORTER, M.D. L. P. STOUT M.D. VD CHARLES C LILB M.D. NEW 1 RK

In accordance with a general scheme suggested by the Director of the Surgical Laboratory to study the phases of repair in the body systems we have selected the problem of repair in the gastro-inestinal tract with the hope that data might be obtained that would be of practical value in the post-operative care of intestinal suture. The small intestine was chosen first because the undergraduate course in operative tech nique afforded abundant material. Later we hope to supplement this work with smilar observations on the large intestine and stomach

The objects of these experiments are first the determination of the hydrostatic pressure that a repairing intestinal wound will withstand xecond the effect of transverse division and suture on segmentation and kird an observation of the gross and microscopic phenomena of result.

HISTORY

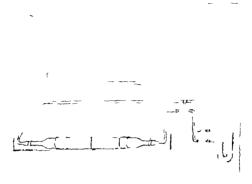

In 1887 Senn (1) described experiments on the production of obstruction voyulus, strangulation and intussusception together with the results obtained from resection and subsequent suture of the intestine. During the course of his experiments he reported though not m detail, a few of the processes of repair. In one senes of experiments he produced obstruction by tying the intestine near the ileocrecal valve. Three to seven days later he performed an fleo-ileostomy or ileocolostomy using decalcified bone plates. One of his dogs died at the end of 24 hours. When the intestine was subjected to hydrostatic pressure no leakage occurred at the site of suture. He believed that absolute physiological rest of the intestine was necessary for perfect healing. He also reported that scarification or chemical irritation of the peritoneum produced adhesions that were both firmer and more rapid in their development than those following simple apposition of serous surfaces by suture. After mechani cal or chemical irritation of the peritoneum

an outflow of blood and lymph appeared on the surface. He also noted that gross vascularization began after 40 hours. At 15 days the mucosa was almost but not quite completely regenerated.

In 1806 Mall (2) presented a detailed pic ture of intestinal repair. He noted that within a few hours after the suture, the serous surfaces were adherent and he believed that fibrinous union took place before the opera tion was completed At the end of 24 hours the inverted cut edges of the intestine showed extensive congulation necrosis After 48 hours in the sules between dead and hyme mucosa enithelial cells of embryonic type were proliferating in all directions. At the end of 6 days there was a downgrowth of glands into the submucosa probably because the needle tore through the bottom of the crypts. Many of these glands were cystic At the end of 14 days the approximated layers of the muscular and submucous coats were united by firm fibrous tissue denuded surfaces of the mucosa were covered with granulation tissue until the crypts and ville had recenerated. On the tifteenth day the mucosa was almost completely regenerat ed. After 24 days regeneration was complete When the mucosa had healed the inverted parts unfolded and the intestinal wall straight ened out into a smooth unbroken line the end of two months, all the coats were fully regenerated.

He divided the processes of healing into our stages krst the immediate fibrinous umon of the serous surfaces second the destruction of the parts protruding between the flaps of mucosa third the regeneration of the mucous membrane fourth the straight ening out of the suture line

Gould (3) continued most of Malls and ings, but noted in addition that the plastic exudate uniting the scrous surfaces extended from 3 to 5 cm beyond the hase of auture At the end of three days some 3 to 5 mm. of fatally injured nucosa had aloughed and the submucosa was ordematous. Many new

I i Diagram i trimanomet

connective ti ue cell appeared in the clot between the approximated scrou urfaces and complete organization took place at the end of the eighth day. In one cale he found that the denuded urface was covered with embry had upithchum at the end of eight day. After 21 day the denuded area was empletely covered by the newly formed muces abut the musculant mucose had not developed. The musculant was appreximated by the contraction of the intervening scar true.

According to you Frey (4 a pla tic evidate clut 1 t gether the approximated serous urfaces of the sutured intestine. He made no direct statement relative to muscular regeneration although in hi drawings of sections taken two day to four months after operation the muscular had not regenerated.

Hoffman (5) howed that small defects in the mucou membrane of the tomach and intestine of dog healed completely A defect of by cm had regenerated completely at the end of 32 days excepting for a small area about 4 mm in diameter. Larger detects were covered with a single layer of epithelium while very large detects were covered with granulation ti ue.

Meek (0) reported that the longitudinal muscular cost of the cat's intestine regene rated in from , to 9 day after division and suture

Cannon (1) in a discus ion of the relative ments of end to-end and lateral anastomosi gives his results from observations made on different animals one four seven and ten days after end to-end union of the intestine He found that in no case was the slightest evidence observed of stasis of the food in the region of the operation. In lateral anastomoses however his found at the end of the days to two weeks a more or less complete bloking of the canal by accumulated hair and undigested detritus at the opining be tween the apposed loops.

TECHNIQUE OF OPERATIONS

The experiments were divided into two series one upon the relatively normal mail intestine and the other upon an intestine that had been previously injured

Series i The animals in this series were dogs of various types unselected and often poorly nounshed. The operations were done by fourth year students who had had little if any previous operative experience. Each

Fig. 4. Movement of chreater cost of Interimes cost hour after end-to-end anisatomosis. Upper tracing made by chreater cost of sum candal to anisatomosis. operation was supervised by an instructor who however did no part of the operation There were three varieties of operations on the small intestine the repair of enterotomies lateral anastomoses, and end to-end anastomoses. The method of suture varied some what, but as a rule an inner layer of through and-through continuous or lock stitch was taken and this was infolded by some form of continuous seromuscular suture suture material was invariably white alk Since the course is particularly designed to teach operating room asepsis special care was taken to maintain as perfect a technique as possible. All the operations of exposing the lumen of the gut were done with a change of towels and instruments between the middle contaminated and the terminal clean stages.

The care of the dogs was as follows. The day before the operation the dogs were given a soap and water bath and the field of operation was cleansed of hair with barrium supplied mixture. All the operations were done in the forenoon and on that day the dogs received no food at all. The ancesthetic used in every case was other. Following all operations the dogs were given as a routine water on the day of operation milk and water the next day and regular diet of bread, ment, and small bones on all succeeding day.

Series B After completing the first series the objection was raised that the experiments were inconclusive since the operations were done on the normal intestine. Consequently we endeavoured to injure the gut by interfering with its blood supply before doing the suture operation Some difficulty was en countered before a satisfactory method was found Ligation of the mesentery which included the vessels supplying a loop of intestine a foot in length had apparently no effect on the viability of the gut Injecting llouid paraffin into a branch of the mesenteric artery or vein was a little more successful but could not be controlled. Sometimes a loop became moderately hyperemic but more often there was no effect at all or there was a general mesenteric thrombosis with gangrene and quick death. Finally a simple effective and easily controlled method was devised a piece of half inch tape was tied about a loop of intestine just tight enough to cut off the venous return while still allowing the entrance. of arternal blood This simulates exactly strangulation of the gut as seen in strangulated hernia volvulus and like conditions. This preliminary operation was done twenty four hours before the second operation which consisted of wide resection of the strangulated gut and end to end ana tomosis In this second series the prelumnary operation was done by the experimenters and the resections and anastomoses were done in some cases by students, in others by the experimenters themselves. The method of anastomoses was that already described

HYDROSTATIC EXPERIMENTS

Technique of experiments. The specimens of both series were handled in exactly the same way. The dog was killed or died at periods from 25 minutes to 114 day following the suture operations. The abdominal cavity was opened as soon as possible after death and a loop of gut was existed which included the area of operation and six unches or more on each side of it. This segment was then treated in either one of two ways. Some had one end tied off and a glass syringe fastened into the lumen at the other. Water was then introduced until the loop was considerably

di tended. During the distention the suture line with under observation for leakage.

The other pecimen, were subjected to me i ured pres ure as follows. After removal from the body the specimen was immersed in wirm Ringer solution and glass cannula were inserted into the lumen at either end and securely tied in place. While the gut was still ubmerged both en ls were connected to the apparatu by means of rubber tubing One of the connected ends (Fig 1 a) led to a water bottle (Fig. 1 b) containing colored Ringer solution This bottle was hung from the calling and by means of a rope and pulley could be raised and lowered to any desired height thu giving various hydro tatic The rubber tubing at the other pre-sure end (Fig. 1 c) was attached to the short arm t the water manonicter (Fig. 1 d). With the

intestine connected to the apparatus the air was expelled from the lumin of the intestine as well as from the various lengths of tubing by raising the water bottle. A by pass (Fig. 1.e.) with stop-cock in front of the manometer allowed for the escape of air without the disturbance of fluid level in the manometer tubes. Next the water bottle was brought to the level of the intestine and the stop cock was opened. The level of the fluid in the long arm (Fig. 1.e.) of the manometer was noted and marked zero particular care being taken to see that this point did not represent either negative or positive pressure.

To obtain positive pressure within the lumen the water bottle was gradually raised to any desired height and the pressures were calculated by measuring the height to which the fluid rose in the long arm. Any leakage

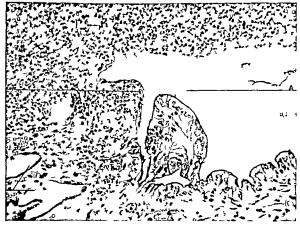

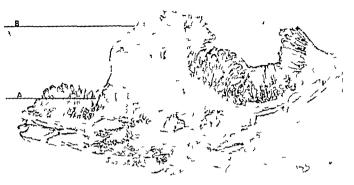

Fig. 3. End-to-end entero enterosiomy z_4 hours, Surgual Pathology $\nabla z_3 = 4$ Sukus between Γ ng muco-a and infolded cut edges of intertinal coat. B newly formed epithelial line

was at once detected for the Ringer's solution in the water bottle was colored blue with acridin blue a vital stain.

Results of the hydrostatic experiments may be seen by referring to Tables I and II thirty two specimens in Series A and B were subjected to various degrees of hydrostatic pressure from within the lumen As the results in the two series were the same they will be considered together Six leaked Of the twenty six that showed no leakage nineteen followed suture of supposedly normal gut while seven followed resection of gut showing more or less severe vascular changes. The experiments were done at from twenty five minutes to 144 days following the suture operations. The measured pressures which the specimens withstood without lenkage varied from 350 to 1400 mm of water (onehalf to two pounds per square inch). That these pressures far exceed any that under ordinary crematances exist within the living intestinal lumen may be readily appreciated by considering for a moment the normally functionatine intestine.

The actual amount of positive pressure in the intestinal lumen is ruo is unknown. The pressure varies considerable even under normal conditions for during the intervals of digestion when the intestine is quiescent, the pressure is practically zero. During digestion however with the passage of the bolus along the canal the internal pressure at a tany one time and upon any given area is certainly positive but the actual amount is relatively alight. Even under abnormal conditions of distention although the pressure is undoubtedly far greater than the average it

lug 4 î dit nelent nico-tim Sirgi al Pathologo Nort Si She naru) u het ec. 11 m. a ad kandrdire Bid nukedin a. . . rel ith granulaten its u and tih n

unquestionably never approaches anywhere near the amount to which the above tibulated perimens have been subjected

Willis Andreus (8) Norking with or intestine and human intestine freshit removed from the body found that they burst at an internal air pressure of from 6 to 10 pounds per square inch. Seni (8) experimenting on the cadaver in a case of enterity, found that the liseased bowel ruptured at an air pressure ct 112 pounds per square inch.

Muller (a) in a recent article on the burst in strength of the abimentary tract found that in cats the average pressure incessary to rupture the jejunum was 28 2 poundsper square inch (1438 mm Hg) and the slum was 48 pounds per square inch (1234 mm Hg). This pressure varied considerably in different cats but was uniform in the same individual. He surther noted that the tear was linear and ran in the long axis of the organ and that the strength of the alimentary trivit lay chiefs in the submucosa.

The six cases of leakage above recorded together with a number of similar cases examined but not included in the tables were with the exception of one case invariably

associated with local injection about the suture line or a general peritoneal intection The one exception was that of a lateral anastomosis done by one of the tudents (Table I No 1) and tested twenty five minutes after completion of the suture operation and fitteen minutes after the death of the dog from the angesthetic. The leakage here was due undoubtedly to taulty operative technique. What the source of the infection was in the other cases could not be definitely ascertained. In many a visible hole leading into the lumen was present, and in these cases the leak probably preceded and caused the That other lesions vithout intection can be present in the intestinal tract vathout interfering with the repair is seen from cases seven and fourteen of Series A (Table I) These dogs died respectively of mesenteric thrombosis and intu-u-ception and yet showed a resistant suture line very slight local infection is of no consequence is amply proved by the relatively enormou pressure that some of these specimens with stood though the microscopic picture was that of infection Given however a marked infection whether accompanied by gross

Fig. 5. Enterorrhiph skitly day after operation Surgical Pathology \ 3 % showing simple) regeneration of muscous roombrane and realignment of muscular coat.

suppuration or not leakage will take place at pressures so slight that they cannot be recorded by the manometer

In connection with this work on the living intestine it is of interest to note the two following experiments. A dog was chloro formed and at death the small intestine was divided in two places and immediately jouncid by end to-end anastomous. One half hour later one of these sections was removed and subjected to pressure of 850 mm. of water without leakage. Two hours later the second section was excised and subjected to a pressure of 1250 mm without evidence of leakage.

VIABILITY OF THE INTESTINE

It has been shown in a previous section that an intestine can withstand within one hour after an anastomous an internal pressure varying between 330 mm and 1400 mm of water. It seemed worth while to determine whether such operations as anastomous interfered with the vlability of the gut.

No better index of the viability can be

offered than a graphic record of the move ments of a loop of intestine which includes an anastomotic suture. A preliminary experiment with a loop of dog a intestine one hour after the repair of an enterotomy showed that this operation did not interfere with the contractions of the longitudinal muscular coat. Such an experiment would not indicate whether the contractions were due to move ments of muscle fibers in close proximity to the injury or to those fibers at a considerable distance from the site of operation.

In order to determine the relative activity of smooth muscle near the site of operation and at a considerable distance therefrom the following experiments were devised:

Immediately after the suture had been tested for its efficiency against internal pressure the cannula which had been tied into the lumen were removed and the loop of intestine was transferred to an oblong dish containing fresh, warm Ringer's solution. The loop of Intestine was then haved by means of two sutures to a glass tube the ends of which were sutures to a glass tube the ends of which were

bent at night ancies. Exactly opposite the two original sutures two other stitches were taken and tied. One end of each of these threads was then passed over a pulley and connected to a recording lever which wrote upon the smoked paper of a slowly moving Lymograph The levers were properly weighted and wrote in such a fashion that when the circular muscle of the intestinal loop contracted the writing point moved upward during the relaxation of the intestinal wall the writing point descended was supplied to the Ringer's solution which bathed the intestinal loop, and the temperature of this solution was maintained at 38 to 39 C by means of a large water bath

The position of the sutures varied in the different experiments so that we were able to study muscle within 5 mm of the site of operation as well as mus le 100 mm from the

line of suture The accompanying illustration (Fig. 1A) is a graphic record made by the circular muscle of a loop of intestine which was excised one hour after an end to-end anastomoses had been made. The lower tracing is made by the circular coat 15 mm cephalad to the suture the upper tracing represents the movements of the circular coat 95 mm caudal to the anastomosis. The mixements of the muscle 95 mm from the site of injury are powerful regular and show very distinct tonus waves. The movements 15 mm from the injury are fairly regular and show less pronounced variations in tonus.

Though it is true that all the movements that we have recorded are comparatively mall this may be accounted for first by the fact that these loops have invariably been exposed to a very high internal pressure and second to the fact that the dogs have received

no food for 12 hours previous to operation. This latter element is probably the more important since Magnus has shown that an animal recently fed shows very much better intestinal contractions than one that has been fasting

Kaled, chiambon

3570 7 days

In all the experiments the movements of the gut which are carried out in close proxim ity to the site of injury are invariably smaller than those made by the intestine 10 or 20 times more distant.

The interval elapsing between the time of operation of anastomosis and the graphic recording of the movements does not modify the strength of the contractions. Thus, in experiments which have been carried out in a dog killed one hour after anastomosis the contractions are no larger than in experiments that have been made four days after a similar operation A moderate amount of acute in flammation about the suture line does not interfere with the movements of the muscle. either near the suture or at a considerable distance from it thus in one experiment the contractions made by a ring of muscle 5 mm from the suture were oulte as well defined as those made 150 mm from the suture line.

Only one experiment was carried out on an intestine after gangrene had been produced. In this particular instance, muscle 60 mm from the suture line contracted well, whereas muscle 5 and 15 mm from the suture line remained absolutely quiescent. This quiescence cephalad to the injured area would seem to be a protective mechanism. It has been shown that when gangrene occurs the suture line does not withstand on increase in internal pressure. Normal movements of the intestine are undoubtedly associated with an increase in internal pressure. And if weakness occurs at the line of suture an escape of intestinal contents into the peritoneal cavity will occur From these experiments then it appears that the inhibition of the intestine cephalad to the suture aids in preventing the escape of intestinal contents into the peritoneal cavity

Strangulation with tape

The movements which have been recorded are not true peristaltic movements. They represent only the segmenting movements of Cannon No attempt has been made to record graphically true peristaltic contractions. Careful observation has never shown a peristaltic wave spread across the suture

The conclusion that may be drawn from these experiments is that despite the very severe operation the smooth muscle of the intestine retains its viability and its segment ing function This function is demonstrable within one hour after the completion of the operation and is present four days after operation. In the presence of gangrene and a leaking suture, these segmenting movements are inhibited cephalad to the suture whereas caudal thereto the movements are regular powerful, and well-defined.

ANATOMICAL AND HISTOLOGICAL OBSERVA
THO S O THE PROCESSES OF REPAIR
AND REGENERATION

From a gross and microscopic examination of the thirty two specimens comprising the two series together with an examination of many similar suture operations done in this laboratory and a comparison of these observations with those of Mall Gould and others a fairly comprehensive picture of repair and regeneration in healing intestinal wounds has been obtained.

In the course of an operation that divides and then sutures the coats of an intestine a certain amount of damage is done. The knife that has severed the intestinal coats and the scissors that have trimmed off the redundant mucous membrane have killed many cells and fatally injured many more Handling the peritoneum has done some damage to its scrous cells. The needle while passing through the wall of the gut injures some of the small blood vessels. It may also tear off the bottoms of some of the glands and ripts of the mucosa and may even carry living epithelial cells along the suture tract deep into the submucosa or muscularis. Finally slight contamination of the tissues in and about the wound is inevitable

As a result of these injuries when the suture operation is completed the blood that has escaped on the free pentoncal surface and between the approximated infolded serous coats coagulates in a wedge shaped mass that plugs the line of suture throughout its entire extent (Fig. 2 A) There is also a certain amount of coagulated blood in the substance of the intestinal wall and about each suture This coagulated blood is no doubt of importance in preventing leakage due to possible faulty operative technique it is not essential in preventing leakage it no technical errors are made would seem probable from the two anastomoses done on the intestine of a dead dog in which no coagula tion of blood took place and yet which did not leak when subjected to extremely high pres-

Depending on the amount of trauma done to the peritoneum and upon the quantity of blood extravasated more or less extensive fibrinous adhesions occur. These developvery rapidly between the line of suture and the surrounding seroul surfaces more particularly that of the onentum.

During the first hour following suture polymorphonuclear leucocytes make their appearance in the region of the wound. They may be seen in and about the engorged blood ve sel invading the coagula and collecting about the buried sutures. Evadation of serum has begun by the end of the first hour It is first noticiable between the muscle burdles of the miss idea.

Degenerative changes in those this uses which are fatally injured by the operative trauma no doubt start at once for it can be seen microscopically along the cut muchae edges thur hours after operation.

Reparative processes also no doubt begin very quickly. The intolded at edges of the inte tinal wall make a ridge which juts into the lumen of the inte tine (Fig. 2) summit of this is composed of the exposed cut edge of the intestinal coats. Somewhere on the loping sides of this ridge are the ninc tions between the living muco as and the denuded area. This junction is often marked by a sulcus (Fig. 4 4) Within 24 hours ubroblasts can be observed problerating just beneath the necrotic tissue and fibrin which cover the denuded area. Fibroblasts can also be seen beginning to invade the edges of the blood coagula in other parts of the specimen. In the sulcus at the edges of the ridge the epithelium lining the adjacent intact mucosa starts to proliferate growing in a flattened syncytial layer over the denuded surface The appearance of this new forming epithelium closely re-embles the embyronal form (Fig. 3 B) The cystic downgrowth of newly formed glands into the submucosa has begun by the end of 4 hours. This was described by Mall but he did not observe it until the 1xth day

During the next three days the congestion the edema and the leucocytosis are on the increase. Grossly, the hbrinous adhesions become progressively himmer and when torn away leave a reddened suture line with swollen edges. Inside the lumen the degen erated and dead tissue is separated from the

living and is cast off. The denuded surface of the ridge becomes smoothed over with a thin layer of fibra beneath which granula tions are springing up. From the sulci on either side the epithelium is growing over this smooth surface beneath the fibria.

In seven to ten days the coagulum disappears and is replaced by new connective tissue This contracts so that it is difficult to tell, microscopically exactly where the hae of approximation is The time required to cover the exposed surface of the inverted ridge is extremely variable. It depends largely on its surface measurements and elevation Mall found it almost covered with a new mucosa after 15 days. In one of our cases it was not completely covered after 38 days. The average is about 21 days. The forma tion of new glands proceeds almost as rapidly as the growth of the new layer of the surface epithelium The newly formed mucosa is at first thinner than normal and has no muscu laris mucose. After two month have passed however it is completely regenerated and cannot be distinguished from the surrounding undamaged mucosa.

After the seventh day the abrinous adhe sions between the suture line and the sur rounding serous surfaces have for the most part, disappeared. Those that remain, be come organized so that by the fourteenth day they are dense and tibrous and can only be torn away with great difficulty pested by Prof W C Clarke most of these also disappear gradually as the months pass the movements that go on constantly within the abdominal cavity by gentle traction probably cause stretching of the connective tissue fibrillæ disappearance of the bloodvessels and gradual atrophy and disappear ance of the adhesion band. It is common to find after one month only a angle narrow band running from the cicatrix in the gut to the omentum or mesentery

The realignment of the intestinal wall which is the fourth and final stage of repair according to Mall was not as complete in our cases as he seemed to find it. In none of the precurens examined by us did the infolded ridge disappear entirely It undoubtedly grows much smaller. The circular muscle

appears to be realigned but we were always able to see connective tusue interrupting the course of the muscle-bundles. Marchane (10) and in this connection The regeneration of the muscle bundles is not abundant enough to bridge small spaces of a few millimeters—if however muscle wound he against muscle wound the scar macroscopic ally would conceal itself in the unbroken light of the fibers. That a certain amount of regeneration of smooth muscle can occur seems certain

The epithelal lined cysts and tubes with adenomatous growths about them deep in the wall of the gut, which were inst observed by Mall, we found in four of our cases ranging from 5; to 144 days after operation. They occur usually about a buried sature and have many polymorphonuclear leurocytes in and about them. Mall believed that they were implanted by the needle at the time of operation. They appear to be of purely pathological interest and to have no surgical significance.

Some remnants of the silk sutures were found in every case. In the older ones there were usually one or more loose ends lying free in the lumen covered with gritty material.

SUMMARY AND CONCLUSIONS

The following conclusions based on the data obtained from the operations on the normal and the gangrenous small intestine of the dog are grouped together for the reason that in both series the experiments were the same and the end results identical

- I The non infected auture line in the small intestine in dogs is very resustant to internal hydrostatic pressure. For at one hour after operation and any time thereafted the area of operation is empable of withstanding an hydrostatic pressure of over one pound per square inch without leakage.
- The clinically infected specimens leaked at minimum pressures.
- 3 To obtain perfect results a proper tech nique is essential. For it is seen that in a dog recently killed the intestine when properly nutured, is capable of withstand ing a pressure of nearly two pounds per square inch without leakage.

- 4 Imperfect technique results in a detect ive suture line. The defects if not too extensive may be sealed by the coagulum which probably prevents leakage.
- 5 The smooth muscle of the divided and sutured intestine retains its viability and segmenting function to within 5 mm of the line of suture
- 6 In an infected case with gangrene around the suture line no segmentation occurred within 15 mm, while 60 mm, away contractions vere powerful and well defined
- 7 Repair in sutured intestinal wounds begins at once with the coagulation of the extravasated blood which fills in the space between the two approximated scrous surfaces. This union becomes permanent in from 7 to 10 days with the replacement of the coagulatin by connective time.
- 8 Repair of the mucosa 1 hirst seen liter 24 hours beginning with a line of an attal epithelial cells extending from the edge of the viable mucosa over the denuded surfa c of the infolded cut edges of the intertual coat.
- o The denuded surface may be covered with an immature mucosa a cirly as the fifteenth day (Mall) but it is usually not completely covered until 23 day after operation
- 10 Regeneration of the mucosa 13 om plete after two months

11 Complete anatomical regeneration of the musculari does not occur. A realign ment of the intolded muscular fibers occurs but it is always interrupted by a thin line of seat tissue.

From the above data we conclude that fluid and lood may be given immediately after operation without danger of leakage in the sutured small into time. If leakage does occur it i due to infection or faulty operative technique.

THE VALUE OF THE DETERMINATION OF THE CHOLLSTEROL CONTENT OF THE BLOOD IN THE DIAGNOSIS OF CHOLELITHIASIS

BY EDWIN HENES Jz. A.B. M.D. New 1 ga. Armstani Admitting Physician, German Hospital Dispensiony.

of a preliminary report on this subject on a preliminary report on this subject on the searches in cholesternamia have been continued in the laboratoric of the German Ho pital. My results seem of sufficient interest and importance to warrant a further more detailed report of my hindings. Much has been written in recent years on

E. Hence J. The Value of the Determination of the Chokeseria Content of the Blood in the Diagnosis of holehrlitaise. J. Am. M. Ass. Irin, 6 the etiology and pathogenesi of gall stones. In the light of our newer researches the older theories became almost obsolete for they failed to take into consideration the fact that cholesterol is a substance which not only is constantly present in the circulating blood and all other body fluids (except urine under normal condition) but that its amount varies considerably under different pathological condition and under different clinical states.

The formation of a calculus, whether that take place in the genito-urinary intestinal or biliary tract, is absolutely a physical process undoubtedly dependent upon an altered chemical state of the medium in which the calculus forms Over fifty years ago Thud icum originated the theory that gall stones were formed by the predpitation of cholesterol and certain calcium compounds as a result of the bile becoming acid. Since the discovery of bacteria, we ascribe chemical changes to bacterial growth and activity Infection and inflammation of the gallbladder certainly play a rôle in the forma tion of gall stones bacterial growth in bile alters the chemical composition of the bile inflammation of the gall bladder mucosa results in epithellal desquamation and the formation of nuclei for gall stones surely the male gall-bladder is just as susceptible to infection as is the female gall bladder and statistics show that 75 per cent of cases of gall stones are found occurring in females. Gall stones are not dependent for their formation upon a primary infection of the gall bladder for we see many cases of cholelithiasis in which the removed gall-blad ders show no evidence of the slightest amount of Inflammation. It is just as logical to conclude that the stones are the primary cause of the inflammation.

The most recent, and probably the most generally accepted classification of gall stones is that of Aschoff and Bacmeister. They classify them as follows

- Instity them as follows

 Pure cholesterol stones.
 - 2 Stratified cholesterol calcium stones.
- Cholesterol-pigment calcium stones, which are most frequently found.
- Composite atones made up of cholesterol and a mantle of cholesterol and calcium.
- 5 Bilarubin-calcium stones, which are seldom found in the gall bladder but usually in the bile passages of the liver itself
- 6 Calcium-carbonate stones which are very seldom found

The amount of calcium and bile pigments found in gall-stones is very trifing From an analysis of many stones—an analysis

which sought merely to determine the amount of cholesterol in relation to the whole stone it can be safely said that cholesterol composes at least 95 per cent of all stones in which cholesterol is a part of their composition.

All authorities in considering the etiology and incidence of gall stones agree upon the following facts

- 1 Most of the cases are found occurring in females.
- 2 A very close relationship between preg nancy and gall stones. Osler in his Prin caples and Practice of Medicine states that 90 per cent of women who have call stones have borne children and Mayo states that oo per cent of women who have gall-stones and have borne children identify the beginning of the symptoms of cholelithiasis with some particular pregnancy. The relation of call stones to premancy was formerly ascribed to the excessive metabolic burdens assumed by the liver during the course of pregnancy burdens which the hver failed to carry on It seems very unreasonable to believe that the body in general and the liver in particular would fail to assume the extra burdens im posed by so normal and physiologic a process as pregnancy

3 A relationship between typhoid fever and choletithiase. It is needless at this time to elaborate on this subject. Cases of gall to the control of the case of the cases of gall stones in those who have had typhoid fever are far too numerous to allow of the assumption of a mere coincident relationship.

The past few years have largely increased our knowledge of choicsterol. The presence of a rather definite amount of cholesterol in the blood under normal conditions has been definitely established. The study of cholesterinamia under pathological conditions has proved the enstence of a hyper and a hypocholesterinamia, and our researches have been sufficiently extensive to permit us to conclude in what diseases, and under what clinical states, we can expect a hyper or a hypocholesterinamia

One of the characteristics of pregnancy is a progressive increase in the amount of choles-

The general of pull-stance. If Am. 31 Am. 1, 21o. Das Chole), the seas. James. 900

Innecest priloteness myth. J Am M. Am 191 April 8, p. 1003. Seventh edition, 200 340

terol in the blood. At term a definite hypercholesterinæmia is found and it persists for some time after the birth of the child.

In typhoid fever as soon a convalescence sets in we note a decided rise above the normal in the cholescency content of the blood. This hypercholesterinamin also per its for some time. We have therefore a hypercholesterinamia in the two most important etiological factors in the genesion gall stones in the genesis of calculi which are largely if not entirely composed of cholesterol.

In interpreting the cholesternamia in an individual case it is of first importance to know the clinical states and diseases which are accompanied by a rise or fall of the cholester inamia from the normal Pregnancy and typhoid fever have already been referred to

The influence of fever is marked and al ways reduces the amount of cholesterol found in the blood. The higher the fever the more marked this influence is

Progressive arteriosclerosis is accompanied by a moderate hypercholesterinæmia. It is during the stage of the disease before the vessel walls become calcined that this hyper-cholesterinæmia is noticed. In the old arteriosclerotics in the type who go on to apoplexies the increase in the cholesterol of the blood is not so marked. In fact our researches show that there is actually a reduction probably due to the deposit of cholesterol in the vessel wall.

In chronic nephritis a hypercholestering ma is found except when the disease has gone on to uramia when there is a decided fall. For details I refer the reader to a recent paper on the subject.

Jaundice is always accompanied by an increase of cholesterol in the blood. This is especially true in all cases of obstructive faundice.

Additional researches in cases of obesity and diabetes will probably show an accompanying hypercholesterinamia in these conditions

The normal cholesterinæmia has been placed between o cor o and o cor8o grams per r con, serum Before proceeding with the presentation of cases I wish to assert very emphatically that despite all that has been said and written for and aguist this and that method for the quantitative determination of cholesterol in the blood. I continue to find the method out lined in detail in one of my first papers.² the best and most serviceable.

The following cases are presented to show that a hyperholesternamia accompanies cholelithiasi and that a quantitative determination of the cholesterol of the blood when properly interpreted can be and is of great diagnostic importance and value. The cases are presented as bir fly as possible and all irrelevant data has been omitted.

CISE I Vale age 38 years admitted to the hospital nath the liagnosis of choleithnism. No fever no laundice no scherosis. Besides the rather typical symptoms of gall stones the patient showed signs and symptoms strongly suggestive of duodenal uter. The stomach snallysis was negative. Here was a case in which it was very lifticult to make a definite pre-operative diagnosis, and on it is whom nothing was found that could influent e the cholesterinamia. The examination of the blood showed the serum to contain no coology of cholesterol to 1 ccm of serum — an amount far in excess of the nor mal. Operation revealed the interesting condition of a duodenal uter and an inflamed gall bladder with stones.

CASE 2 Male age 58 Temperature for F alight iterus moderatie sclerosis no evidence of nephritis Patient has had attacks of cohe and paundice at intervals. On admission to the hospital the symptoms were referable to the gall bladder Wassermann reaction negative. Here we have a case in whom there exists clunical conditions which conflit is as far as their influence on cholesterianisms is concerned. The fever tends to reduce while the slight jaundice and eclerosis that to increase the cholesterol content of the blood. Blood examination showed 0 cos18 gr cholesterol per 1 cm. serum an amount difficult to interpret under the circumstances. Operation revealed a cholecystutis with gall-attones.

The influence of fever on the cholesterol content of the blood is a very definite one and oliverys reduces it. One must constantly bear this in mind in determining the cholesterinemia in the making of a diagnosis. The following two cases clearly show the influence of fever

CASE 3. Female, no 47 years Uruse negative for nephritis no jumplice, no sclerosis. Tempers ture of F in past four days had slowly come d wm from 3. F. White blood-cells, 2 coo polymiclears, 84 per cent. Symptoms referable 1; gall-badder and a diagnosis of empyema of gall was made. Blood showed o.co 31 pr. Cholesterol per 1 ccm. serum, a practically normal amount. Operation revealed an empyema of the gall-bindder and gall-stones. Eight days after the cholesyeretomy, during which time 900 ccm. bile had been drained (outstiffing on absolute loss of cholesterol to the body), with the temperature at 100 F the blood showed 0.0021 pt of cholesterol to the body).

CASE 4 Female, age 41 years. Urin negative, no sclerosia, no jaundice. Two weeks after a ventral suspension for uterine prolapse, the patient began to complain of severe epigastric pain, and showed signs and symptoms referable to the gallbladder Temperature 102 6' F white blood-cells, 23,400 polynuclears 85 per cent. Diagnosis acute cholecystitis. Patient gave no hist ry of typhoid fever nor did she give any evidence of ha ing it at the time. The blood showed o oo os gr cholesterol per 1 ccm, serum. Operation showed an acute suppurative cholecystitis with gall-stones. A few days later a positiv Widal reaction was obtained and a culture taken from the gall-bladder at the time of operation showed bacillus typhoms. A week after the cholecystectomy with the temperature 100 F the blood showed 0.00253 gr

cholesterol per 1 ccm, serum. CASE 5. Female, age 36 years, admitted to the hospital with a diagnosis of acute appendicitis. Temperature 100 F. Urine showed heavy trace of albumin, and much pus occasioned by a purulent vaginal discharge. Subsequent urine showed no evidence of nephritis. No jaundice, no scierosis. The acute abdominal symptoms were referable to the right hypochondrium and kidney region, and while under observation, symptoms a greated those of duodenal ulcer and gall-stones. The blood showed 0.00143 gr of cholesterol per 1 ccm. scrum, an amount just about normal. Ten days after admission the nations was operated upon and a definite pre-operative diagnosis of choiclithiasis was made. Operation revealed an absolutely normal stomach, d odenum, and gall-bladder and a diseased appendix, which was removed. Here in my opinion, we had, or rather the surgeons had, an opportunity to make a definite and correct pre-operative diagnosis, in a case which was rather puzzling.

The following case was especially interesting to me for it chanced to put my ideas on the subject of cholestermemia and chole hthiasis to a severe test.

CARF 6 The patient a physician, about 36 years old, was referred to me by a colleague, an eminent surgeon in New York. At the tim the blood was taken to examination the patient had no

fever urine was negative for nephritis, vessels showed no aclerosa, and he was very slightly jaundiced. The blood and urine did show a trace of bile. Clinically w were dealing with case f cholelitheast, with a history f four years. Four days later the patient developed pronounced jaundice which came o rapidly and the Yray report, thickened gall bladder with shad suspicious of gall-stones greatly strengthened the surgeon s faith in his diagnosis. The xaminati n of th blood showed oo o gr cholesterol per Under th circumstances, amount certainly not in f vor of gall stones. About month later the patient was brought t the hospital, his joundice had markedly diminlahed (nd he gave no hist ry of having passed stone) and an operation per formed The gall bladder as perfectly ormal, and a small lymph nod removed sh wed inflam mat ry changes W all cam to the conclusion that we had been dealing with a case of catarrhal jaundice. A proper I tempretat in and recognition

In presenting these cases I have selected from a series of more than too cases those which show not only that a hypercholester fazzma accompanies gall stones but that a correct pre-operative diagnosis can be made in those difficult right sided abdominal conditions which so frequently simulate one or the other of the following conditions appendictlis cholehthiasis duodenal ulcer and personnel adhesions. My sories of cases show that a cholesterol d termination and a proper interpretation of the amount found is almost invariably of distinct value not only in diagnosis, but in the therapeutic in diference.

of the alue of the cholesterol determination would

have avoided an operat o in this case.

CASE? Male, so 5 Temperature 90 8° F. Union negative no sciences, no joundles symptoms referable to stomach gall-bladder right kidney and appendix, case in which cholesterol determination could be of value. Blood showed oo of gr the lesterol per corn serum and under the circumstances a disposals of deronic appendicitis was made. Operatio revealed normal gall-bladder stomach, and duodenum, and a chronically inflamed appendix.

CASE 8° Male, age 33 years. Temperature 100

F Urine sh wed no evidence of nephritis, no scierosis, no jaundie. Stomach analysis negative symptoms were definitely related to the gall-biad der sufficiently characteristic to warrant a pre operative diagnosis of chelenblaist. Cholesterol determination abowed ont of gr per 1 ccm serum an amount opposed to the diagnosis made. Operative new proposed to the diagnosis made. Operation revealed a normal gall-hiddeder with Link, but no stones, and a chronically inflamed appendix.

In justice to my contention and in further ince of the interest of the cases presented. I rish to add that the pathological diagnoses in individual cases have been taken to in the groot of the Lathological Laboratory.

Cash to The till wing case a one ir bih I more no operative finding to present. It is never Temperature for 4 F Unio n'agritic light telerosis White blord ells 1 000 polymor phonuclears of percent. No jaun'll e n'admissi p. at which tim a liagnosi of appendictis (with reservation; vas made. The ymptom were all referable to the upper abdoming but without den nite local signs other than ten lerres o er the gill bladder Blood canunation at the time howed 0.00234 gt cholester liper i i m serum an amount which in the pres netiter of tor 4 F is de cidedly above normal and under the cir umstances strongly in taxor of gall stones. The day after admission without any new symptoms jaunti e developed I ten las later the temperature reached normal the jaun h e had disappeared and all symp ome had vani hed with the result that the patient insisted on being discharged it in the hos-pital. In my opinion he were without doubt dealing here with a case of cholelithiasis

CASE II Here is another case which did not ome to operation. I present it because of the decided hyperch lesterinemia tound. Male age scierous Sympt ms were relevable to the right hypochondrium and were strongly suggestive of ulcer of the stomach or duodenum. The blood serum showed o 00304 gr holesterol per 1 cum The patient left the hospital refusing operation This is just the type of case in which the cholesternnemia has been most helpful. A case in which the symptoms suggest either an ulter or gall-stones, and in which the cholesterinemia is decidedly above normal (no other clinical cause being found that could account for the hypercholesterinæmin) Such a case is usually one of cholelithiasis, and my experience forces me to maintain that opinion despite roentgen ray indings

CARE 12 Female age 46 years. Temperature for F White blood-sells 12 000 polymorpho-nuclears 81 per cent. No jaundice no sclerosis no nephritis stomach analysis negative. Symptoms referable to stomach and gall bladder. The blood showed 0 00392 gr. cholesterol per 1 cemserum. This case also refused operation, but a

diagnosis of cholelithiasis is the only one to make under the circumstances even if the temperature had been normal

The following case is recorded to show a type in which it is very difficult to properly interpret the chole termemia

Casi is Femal age 68 year Urine sh as albumin hyaline and granular casts no taun lice moderate al rost Symptoms ref erable to toma hand gall bladder. Ga tri analy sis negative. The blood serum showed 0.00 6, gr cholesterol per 1 cum. We have here an adult femile with the sclerous one would expect and evidences of a nephritis to conditions which in then elves are accompanied by a hyperchol t ringmia. On annot doen fupon the chol esterinemia for a definite hagnosis in case of this wrt. Although the case refused operation the I ray showed a large distinct stone in relation to the duodenum. In the straightforward undoubted cases if cholelithiasis we are perhaps not in need of further aids in diagno is. In my experience I have not seen a case of gall tones verified by operation without an appreciable hypercholesterm æmia.

CSE 14 Female age 43 Temperature 100 F Urine negative no Jaundice no aclerosis Clinically a case of cholelithiasis Serum cholesterol 0 00301 gr per 1 ccm. Operation chronic ulcera tive holecystusis with gall stones.

C48L 13 Male age 43 years to fever no jaundice no sclerous no nephritis Diagnosis cholelithiasis berum cholesterol thowed o coa56 gr per 1 cm. Operation Chronic catarrhal cholecystitius with gall stones.

Cyse 16 Female age 3 years Temperature 204 F \ \text{o} selerous, no nephritis no jaundice (Had been jaundiced two months ago) Stomach analysis negative. Diagnosis cholehthiasis Serum cholesterol o coups gr per 1 ccm. Operation Cholecystitis with gall stones

CASE 17 Female age 40 years No fever no jaundine no selerosus, no nephritus Stomach analysis negative large tender tumor mass in relation to lower border of liver Diagnosus chole-lithnasis Sertum cholesterol 000-20 gr per 1 ccm Operation Chroni suppurative cholecysticis with gall stones.

My researches along these lines have convinced me that a cholesterol determination when properly interpreted is of real value in the diagnosis of those obscure conditions whose symptoms focus attention to the right side of the abdomen. Modern \(\cdot \) ray tech inque has materially helped us in clearing up these same difficult cases and especially does that apply to lesions within the stomach and duodenim. Roentgenologists must admit

that they have, as yet, failed to reach a sense of security in the \ ray diagnosis of gullstones. In the following cases in which I mention the \ ray findings, I do so merely to emphasize the importance and value of serum cholesterol determinations

CASE 18. Female, age 50 years. No fever no penhritis, no laundice never preenant, never had typhold f ver Symptoms are abdominal pains closely simulating those of gell-stones. White blood-cells, 0400 polymorphon clears, 68 per cent. Stometh analysis negative except for low addity no sclerosis had never been faundloed. X ray report Shadows suggestive of gall-stones. The serum-cholesterol equaled 0.00200 gr per 1 cm. an amount not sufficiently high to be in favor of gall stones. After observing the case for several days a diagnosis of gall-stones was made. Operation revealed a perfectly normal gall-bladder without stones, and some adhesions about liver and spleen, CASE 10. Male age 46 years. Temperature co to 100 F (the day previous had been 10 F) Moderate jaundice, urine negative. Symptoms referable to right upper quadrant of abdomen, and the case impressed us as a case of gall-stones

Serum cholesterol showed 0.00317 gr per r cm. and the X ray department reported "Mottled shadows suspicious of gall-atones. Operation revealed call stones.

CASE 20. Female, ago 46 years. No fever no jaundice, no scierosia, no nephritis. Symptoms definitely relative to the gall-bladder and she gave a history of repeated attacks of pain and faundice. The blood examination showed copies or cholesterol per 1 ccm, serum and the report from the X-ray department was in substance, no gall Operation showed a chronic ulcerative cholecystitis with one large pure cholesterol stone, a type of stone which does not show up well on the X-ray plate.

CASE 2 Female, age so years. Temperature No jaundice, no nephritis, no scierosis alightly obese. Symptoms were referable to the gall-bladder. The blood showed 0 cog 1 gr cholesterol per com. serum, and the h ray report read "No evidence of gall-stones. Operation re vealed an inflamed gall-bladder containing six large

cholesterol stones.

Male, age 18 years. No fever no faundice, no nephritia, no scierosia. Never had typhold fever For the past two years he has had symptoms suggesting duodenal ulcer or gall-stones for a long time had duodenal feeding seven months ago appendectomy without any relief Vomiting has always been the chief symptom. The blood showed 0.00107 gr cholesterol per 1 ccm. serum, and the A-ray department reported shadows suggest ing gall-stones. A diagnosis of cholclithiasis was made. The findings at operation were practically negative, except for adhesions between the gall

bladder liver and duodenum sall-stones or ulcer were not to be fou d.

Case 3 Female, age 45 years. No fever no jaundice, no nephritis Symptoms referable to stomach. Despite negative stomach nalysis, we were, apparently dealing with a case of gustric ulcer that, at least, was the clinical picture pre sented. The blood showed 0.00 84 gr of cholesterol per 1 ccm, serum, and the X-ray department reported one large gall-stone. A second \-ray parture she ed three large stones. Operation revealed a cutarrhal cholocystius with gall-stones. The gali-bladder contained three large stones and many very small ones. There was no evidence of an older of the stomach

It will be noted from these latter cases, that the cholesterol determination correctly foretold the condition eventually found at operation a claim whi h I cannot make for tĥe ∖rav

CASE 24 Female age 48 years, was admitted to the hospital complaining I pains and welling of lower extremuses and pain in lumbar regions. No fever nephritis, o jaundice (had been laundiced two years go) no scierosis Wasser mann reaction negative whit blood-cells 5500 polymorphonuclears, 71 per cent harmon bin, 70 per cent. Stomach analysis showed to free hydrochloric add, 64 total and no lactic add, and no blood. The physical examination sh would the lower border of the liver reaching to a line connecting the anterior uperfor spane of deam with the umbilicus. Its surface was smooth Below the edge in the gall-bladder region was a rounded nodular hard mam, the size f a wal ut hich can be separated from the liver and is tender Underneath the liver and more posteriorly in lumbar region, a similar mass can be felt. V Virchow glands felt. I present this case in more detail because of its The patient s general prearance sug gested malignant disease. I neurological examina tion further suggested the probability of spinal cord metastases. The \ ray examinations of the spinal column and abdomen were negative. A cholesterol determination howed 0.00156 gr per serum. Despite this hypercholesterinemia, a diag nosis of carcinoma of liver or colon was made, and an emploratory operation performed. The surrecons were very much surprised t find gall-bladder full of stones it was the mill-bladder that was the mass originally felt. No evidence of mallgrant discuse was found. Subsequent neurological examination of the patient resulted in the conclusion that the symptoms at first thought to be due to mallement cord metastases were due to a multiple sclerosis.

CASE 25. Female, age 20 years. Married last child 8 months ago. Symptoms referable to well bladder began a months ago. Never jaundleed and not now Temperature 100 F White blood-cells 7800 polymorphonuclears 7 per cent. N neph

ritis, no sclerosis Clinically a case of cholelithiasis Cholesterinæmia o 6025 gr per 1 ccm serum Operation revealed a few small stones in the cystic duct

CASE 26 Female age 35 years. Temperature 98.8° to 100.2 F. No nephritis no jaundice no sclerous. Four pr gnancies last one eight month ago. Symptoms referable to right upper and 1 wer qualitants. Stomach analy is nestine. Chilestermamia 0.0023; gr. per 1 c.m. serum. Operation revealed a gall bledder ontaining a t. small stores and a hromatills inflamid at pendix.

CASE 27 Female age 66 v ir Ten preg nancies last 18 years ago | jaundice Fem perature had been 102 F the day before the blood was examined. Unine should a trace of all umin a few granular casts and the art nes showed mod erate sclerosis. The blood pr-sure was 161 mm White blood-cells 5,400 prlymorphonucleurs 86 per cent Symptoms referal le to the right lumbar region Stomach analysi sh wel no free hydrochloric acid and a liminish d total acidity ically we were lealing with a use of gall stones With a coincident eviden of a phritis and some selerosis, a mixl rate hyper holest rimemia was to be expected. The blood showed a 20331 gr cholesterol per 1 ccm an amount waich in the present of the 102 fe er f th day before must be looked upon as a decited increase have the normal. In this case I have no post perati e huding patient left the hospital refusing peration.

In three private cases which came under my observation in whom there was absolutely no doubt as to the diagnosis of gall stones and in whom there were no coincident conditions that would influence the cholesternaema. I obtained ingures if 0.00100 0.00320 and 0.00347 br cholesteril per 1 cm verum. None of these cases ha as yet come to operation.

We knes of ases in ludes many which at operation showed either ulcer of stomach ulcer of lundenum intestinal adhesions chrome appendictus or carcinoma of pylorus conditions which very frequently are to be differentiated from cholelithians. Be cause I do not consider the facts of interest I shall not present those cases whose cholesterinamias verified the operative findings when those indings were other than gall stones.

Through the courtes, of Dr Allen O Whipple I was permitted to examine the blood of several cases referred by him from the services of Drs Brewer Elliot and Longcope of the Presb ternan Hospital

Case 26 Female age 37 years Sixteen preg nancies no jaundice no wierous no nephritus Temperature 101 F. White blood-cells 12500 polymorphonuclears 80 per cent. Symptoms and physical signs all referable to the gall bladder Serum-cholesterol amounted to 000450 grs. per 1 cern and would have been even higher with normal temperature. Diagnosis of chilecosticis with gall stones was made and operation verified it. About 18 calcium bürübin holesterol stones were found in the gall bla liter.

CASI 30 Female age 33 years. Typhoid fever 2 years ago. Frescue havors dates back seven years and began while she was four months pregnant. Has had four attacks in seven years on epigastric pain nausea vomiting and jaundice. At presert no fever no neighbrits no selerous, but very slight 1 teru. Serium-cholesterol showed oo 2 gr per 1 ccm serium fibe diagnosis of choleluthas wa virtued at operation and niteen small mulberry like. Indesterol calcium bilirubin stones found.

Cast 30 Female age 54 years Pain in epigastrium nausea vomiting chills fever and jaundine coming on in atta 48. First attack axteen vers ago after her bits pregnancy has been pregnant four times since then. At the time the blood was examined the patient was slightly jaundined had no fever no selerous. White blood cells 27300 polymorphonuclears 00 per ent Wassermann negative. Unne showed very faint trace of albumin and 25 per c nt sugar. The blood sugar equalso 1,10 per cent. Chelsternarmin in this case am unted to 00076 gr per 1 ccm serium. This patient was not operated on, but during her stay in the hospital several facetted gall stones were pussed in the nees.

In reviewing the last case the question immediately arises why was not the amount of cholesterol in the blood even higher for the jaundice and the diabetes are in them selves accompanied by a hypercholester inæmia. In attempting to answer that question the whole subject of the local deposit of cholesterol must be considered Gall stones are not the only local deposits of choles terol In arterio clerosis and atheroma of the gorta it has been repeatedly demonstrated that cholesterol is deposited in the walls of the blood vessel. The yellowish plaques found in the atheromatous aorta are largely composed of cholesterol and these plaques are not the result of an intiltration, but rather a deposit. The older the process the greater the deposition and eventually the vessels become impregnated with lime salts. It is only in this stage of arteriosclerosis that we

see our apoplexies. And it is during this stage that the cholesternæmia is not as marked as during the progressive stage. Can we not conclude that the blood-cholesterol is decreased somewhat, because it is slowly becoming deposited elsewhere?

The chronic nephrities who go on to socalled albuminuric retinitis also show the effect on the amount of cholesterol in the blood of the deposition, or in this case infiltration of the retinal tasse with cholesterol. It has been shown that the retinal plaques are composed largely of cholesterol and it has further been shown that cases of nephritis with retinitis, have less cholesterol in the blood than cases of nephritis without retinitis. Can we not again conclude that this diminution is the result of local deposition or infiltration? This same theory I am applying in cases of cholelithiasis. The constant deposition of cholesterol in the gall bladder in the formation of gall stones must slowly deprive the blood of some of its cholesterol Perhaps this would explain some of the comparatively low figures we get despite the presence of gall stones. This then would bring up another point in the proper interpretation of the cholesteringmia in individual cases. In the last case presented the patient gave a history of sixteen years. Had we examined her blood ten years ago the amount of cholesterol in the blood might have been considerably higher than 0.00276 gr per 1 ccm. A careful history to deter mine the onset of the gall bladder trouble is, in my opinion an important element in the interpretation of the cholesteringenia.

CARE 3 (from the Presbyterian Hospital) Female, age 50 years. Has had five attacks severe, colicky epigastric pain, radiating to the back, with vomiting and jaundice. Has never had ty phoid fever and has been pregnant nine times. No scierosis, no fever, no nephritis very slight icterus. Serum cholesterol amounted t only 0.00 77 gr per 1 ccm, and yet at operation, the gall-bladder was found full of small stones. In this case we did not obtain a careful history

CARD 32 Male, age 63 years. Temperature xoo F Moderate sclerosis, slight jaundice. Urine showed heavy trace of albumin, but no casts. Symptoms and physical signs were all referable t the gall-bladder. Here again, the comparatively low figure of 0.002 4 gr of cholesterol per 1 ccm. serum was found and the operation revealed gall stones. In this case, also we have no accurate history of the duration of the trouble. In my opinion, we must, in the future, ask ourselves. If this patient has gall-stones how long has he had them?

Case 33 (from Presbyterian Hospital) Female, age 43 years. Had been o th Medical Service for two months with pyelitls when present attack began Pain and tenderness in right upper abdom inal quadrant with vomiting. Tender mass in the remon of the gall-bludder. No j undice no ederosis no nephritis Temperature 10 F White blood cells, ro coo polymorphonuclears. 78 per cent. Whilal negative Wassermann negative. Has never had typhoid fever and has not been p canant. The blood showed o oo o gr of th lesterol per com, serum an amount which must be looked upon as high in the presence of o F fever Operation revealed 65 gall-stones, with evently formed layers of cholest rol

Case 34 (from Presbyt rum Hospital) Fe male age 36 years. Onset of troubl six years ago while pregnant the twelfth time Never had typhoid fever Temperature o F White blood cella, 8,000 polymorphon clears 80 per cent Was-sermann negative h jundice n sclerous, no nephritis Pains in right upper abdominal quad-rant simulating gall tone cole. Serum-cholesterol amounted to oo og gr per cm an amount in favor of cholelithusis under the circumstances. On operation, a markedly thickened gall bladder containing several ounces of post and to gall-stones

were found

Cass 35 (from Presbyt ria Hospital) Female, ago 35 years Three p egnancies ever had typh id fever Temperature co., F No nephritis no aclerosis, slight icterus Whit blood cells 0,100 polymorpho uclears. 4 per cent Wassermann negative. Symptoms strongly suggestive of gall stone colic. The blood she ed o co 7 gr cholescm. serum At operation, the gall terol per bladder was found large and thick, c ntaining 6 ounces f thick vascid bile and three gall-stones.

Case 36 (from Presbyterian Hospital) Fe male, age 38 years. For past six months engastric pain, vomiting, and for past few days cterus Has been twice pregnant. No scierosis no fever no nephritis. Definite tenderness in right upper abdominal quadrant where a mass can be felt. Blood showed 0.00256 grams of cholesterol per 1 ccm. serum. Operatio showed the cystic and common ducts distended with soft mushy material and many small stones.

CASE 37 (from Presbyterian Hospital) Fe-male, age 43 years History of epigastric pain radiating to back and right scapular egion, fever vomiting In past five years has had several such attacks. Has never had typhoid f ver has never been pregnant. At present, no jaundice, no fever no nephritus, no scleroris. Exquisite tenderness over the galf-bladder and a mass is felt. Cholesterinemia amounted to coass gr per

serum. Operation revealed a distented gail blad. der and a pure cholesterol stone impa ted in the evatic duct

Case 38 (from Presbyteman Hispital male age 50 years. History of pain in right unixr quadrant onset sudden six months ago with pain in region of gall bladder Has half our attacks and intermittent jaun lice Typhoid fey r it 14 years Seven pregnancies. At present no seletous no fever no nephritis but jaundt d. Chol sterinæmia amounted to o cos 1 gr per 1 m strum operation a very interesting condition was found No gall bladder was to be found the only uggestion of it was a small narron strip of tissue where the gall bladder should be Th common duct was dilated to the size of a ting r In the I wer part of the duct a single oval gill stone was found. It ha! a cholesterol nucleus and a cul ure from the cent r of the stone showed buildes profes

These 38 cases presented are sufficient to show that in the great majority of cases a hypercholesternremia recompanies chole lithiasis It is needless to enumerate more They also show that the cholestermamia must be studied in relation to the clini al condition of the patient at the time the blood is examined before it can be properly interpreted and made to issist in deriving at a correct diagnosis. We must make the necessar allowances for the presence or absence of fever jaundice nephritis progressive arteriosclero is and must also take into account the duration of the process of deposition in the gall bladder. These cases further show that a classical picture gall stones can prove to be a duodenal ulcer and a classical picture of duodenal ulcer can prove to be gall stones. It is in just such cases that dependence upon a cholesterol determination when properly interpreted will be of great help in making a correct diagnosis and at times cholesterinemia has almost shamed the \ ray

A hypercholesterinæmia in the absence of arternsclerous jaundace and nephritus does not necessarily mean the presence of gall stones. In my opinion we must realize that we are dealing with what can be likened to a diathesis, a cholesterol diathesis diathesis is either distinctly pathological in that it may result in arteriosclerosis local or general or in gall stones or it manuests itself as a protective agency as in the infectious discuses and nephritis. Only a careful metabolic study can clear up the many doubtful a pects of the subject of choles

terina mia The following are cases in which the choles terin rmia wa. not indicative of

operative findings (ASE 30 (from Presbyterian Hospital) male age ; year no fey r no jaundi e no sclerono nerhmus. No typhoid fever and has been t regnant is times Sums and symptoms referable to the appendix Blood showed 0 002 7 gr cholesterol per 1 ccm serum but at operation a perfectly normal gall I ladder was found. Diagno-

si appendicitis No fever no Usi 40 Male age 53 year naundice no nephritis moderate sclerosis hr t symptoms were referable to the right kidner subsequently attention was attracted to the gall bladder (holesternamia amounted to 0 00330 er per i com serum a figure that under the cir umstances is suggestive of gall stones. Operation revealed a perfectly normal gall bladder stomach and duodenum I have no further post-operative record As for th arteriosclerosis in this case I am not willing to state that it alone was responsible for the hypercholestering mia

CASE 41 Female age 64 years giving symptoms of gall stones to fever no jaundice no nephritis Gastro-intestinal tract negative by X ray examina tion This patient had marked arteriosclerosis. Cholesterinæmia amounted to o 00310 gr per i ccm serum an amount which the sclerosis in this case could account for The operation revealed in testinal adhesions and a normal gall bladder

These three cases are the only ones in a series of 128 (including the cases presented in the preliminary report on the subject) in which the cholesterol estimation of the blood did not foretell the actual condition eventually found at operation or the definite diagnosis made on the discharge of the patient from the hospital. And in no case of cholehthiasis. verticed by operation did the blood fail to show a hypercholesterinæmia Naturally those cases which showed coincident conditions which influenced the cholesteringmia are not included in that statement.

We cannot overlook the interest and especally the importance of these facts. They prove that a properly interpreted cholesterol determination is of great help not only in the diagnosis of cholclithiasis but also in the differential diagnosis of those diseases which so often simulate cholelithiasis

DEPARTMENT OF TECHNIQUE

SURGICAL REPLACEMENT OF THE PROLAPSED KIDNEY

B DOUGAL BISSELL, M.D. F.A.C.S. New YORK Attender Ferenz Woman Beredal

CINCE Hahns instal effort to mave the prolapsed kidney and restore it to its normal place and efficiency there have been devised many surgical procedures with the same conservative object in view. But the evolution of nephropexy from 1881 has been alow and varied. The original plan namely splitting the fatty capsule down to the outer portion of the kidney stitching this capsule to the wound and packing the wound with carbolized gause, has been variously modified by those who followed Hahn, but all efforts to permanently fix the kid-

ney were countly unsatisfactory Senn in 1807 appreciating the failure of preceding methods, instituted a radical change, namely the suspension of the organ by means of a strip of gauze passed around the lower pole. In this way he hoped not only to make fixation more certain but to restore the kidnes to its normal position. Deaver and Da Costa modified Senn's method by passing a sling around each pole. Fisher employed two decalcified bone drains and Beyer two rubber drains in the same manner Chambers in 1901 passed a catgut anture around the lower pole. In some of these procedures the fatty capsule was removed but in none of them was the fibrous capsule utilized directly or indirectly as an extra means of sup-

Another important improvement in the technique of fixation was made by Lloyd who reflected the fibrous capsule of the convex border of the kidney so that the denuded surface might be apposed to the abdominal wall for fixation. To maintain the kidney in position until union took place Lloyd and some who followed him passed autures through the kidney substance and both attached and reflected layers of the fibrous capsule. Others utilized the fibrous layers for support by stitching them in the wound.

Previous to October 25 1907 I employed the technique then in common use namely exposing the convex border of the kidney and maintaining the organ in position by means of the sutures

passed through the reflected fibrous layers and through tusses in the region of the wound My results were most discouraging and I became convanced that one of the chief faults in this tech nique was the failure to maintain the kidney in position long enough for firm union to take place. I ressoned that as the abrous carsule varied greatly in thickness and strength, it was not dependable and constituted an element of weakness in technique so that when force from above was directed against the kidney after operation such as results from vomiting and deep breathing the sutures might tear through the fibrous layer to which they were attached, and that if we could adopt some method by which the dependence upon this capsule for support could be eliminated the problem of fixation would approach solution. This reasoning led me to pass about each pole sustaining sutures of chromic caterut. Results of this technique showed me there were a sufficient number of unantisfactory cases to convince me that the technique failed to meet all conditions. These results proved to me that the convex or outer border was too limited a surface for fixation and that even though the kidney became attached its position was not always relatively normal and interal motion was permitted. As the result of such reasoning I adopted a radical change in prepar ing the kidney for fixation i.e. exposing the greater part of the posterior surface and using the fibrous expands to prevent the fat from wedging its way between the apposing surfaces.

Such is a brief résumé of the important steps in the evolution of the method herein advocated,

In discussing the surgical problem of permanent replacement of the prolapsed kidney the approach to the organ demands our first consideration. The posterior or lumbar route is now generally selected but the technique of approach varies and has not yet been standardized. In the technique of approach which I prefer the initial incision begins over the twelfth rib about five centimeters from the spine a little above and to Read before the Medical Socrety of the County of Kew York April 28, 914the inner ide of the angle formed by the last rib and the erector spina and extends downward and outward ten or more centimeters to a point near the crest of the ilium immediately above Petit's triangle. The tissues covering the erector spinge and the latissimus dorsi are dissected from these muscles so as to completely expose them to view The next incision is made along the line of attachment of the terminal tibers of the latissimus dors; to the erector spins and lumbar fascia and this portion of the latissimus dorsi is freed and transferred to the outer margin of the wound The lumbar fascia or strictly the transversalis aponeurosis is completely exposed when the lumbar portion of the latissimus dorsi is thus transferred to the outer margin of the The lumbar fascia is now incised at its upper portion or superior triangle immediately below and parallel to the twelfth rib This incision is extended as necessity demands. The lower area of the transversalis portion of the intra abdominal fascia is thus exposed, where it divides to form the fascial capsule of the kidney and the last dorsal nerve is seen following close to and parallel vith the inner margin of incision

In the upper angle of the lumbar fascial in casion the retrorenal or posterior layer of the fascial cipsule is seen and incision of its posterior layer exposes the fath; capsule through which the kidnes is directly approached by blunt dissection. The fath; capsule is now separated by the inger from its attachment to the kidnes excepting about the poles where the inger is hooked into the remaining itssue of the capsule and one or the other pole directed toward the wound. When the kidnes is delivered the remaining attached portion of the fath; capsule is freed and both kidnes and ureter examined carefulls.

A crescentic incision of the fibrous capsule is now made. This incision begins practically on the convex surface near the upper pole extends on the posterior surface of the kidney to within about one centimeter of the hilum and continues to the convex surface near the lower pole Two sustaining sutures of silk worm cut kancaroo tendon or chromic gut are now passed com pletely around the kidney one about the lower and one about the upper pole. They are passed in the following way The one surrounding the lower pole penetrates first the free portion of the fibrous capsule near its juncture with the kidney and about one half inch from the center of the convex border. In its course around the kidney it penetrates the anterior surface of the fibrous capsule midway but only sufficiently to keep it

in place. It is now palsed around the inner or concave border close to the lower limits of the hilum and then through the attached portions of the hibrous capsule remaining on the posterior surface. The suture encircling the upper portion is passed in like manner and the ends of these utures are clamped to keep them in position until the kidney is replaced. Three or more small catgut sutures penetrate the margin of the freed hibrous apsule. These are used after the ladney is returned to anchor this portion of the capsule to the under surface of the lumbar fascia.

None of the fatty capsule except such as may remain attached to the lumbar muscular area is As a rule all of the fatty capsule is removed. forced below and in front of the kidne when the organ is replaced where it is retained by the an chored abrous capsule. The inner ends of the sustaining sutures are now passed in the upper angle of the wound through the lumbar muscles penetrating them well to the inner side of the In t dorsal nerve and out through the skin. The outer ends are passed through the muscular tusue immediately below the twelfth rib and out through The several catgut sutures which are attached to the margin of the freed fibrous cansule are now anchored to the under surface of the lumbar fascia near its cut edges. The freed fibrous capsule being thus anchored to the under surface of the fascia acts like a shield to prevent the fat in the immediate region from being forced between the posterior surface of the Lidney and the quadratus lumborum

The fascial or aponeurotic incision is now closed with No 1 or No 2 plain caterut sutures care being taken to avoid the last dorsal nerve which can be plainly seen crossing the inner margin of the wound One or two interrupted catgut sutures may be necessary to approximate the tibers of the transversalis and internal oblique The latissimus dorse is now returned to its position and its cut edges sutured to its original line of attachment with a continuous plain catgut suture No 1 or No cutaneous structures are approximated by one or two interrupted catgut sutures and the skin edges united by any method preferred. The sustaining sutures at the upper angle of the wound are ued over a small roll of iodoform gauze the lower suture being tied first so as to elevate the kidney as much as possible. If kangaroo tendon or chromic gut be used for the sustaining sutures they can be brought out through the skin or not as desired by the operator

Post-operative care extends over three weeks. In dressing the wound care should be taken not to restrict the motion of the chest or abdomen. It is usually not necessary to referes the wound until the seventh day. The askn autures are removed on or after the twelfth day. The nik worm-gut autures are cut to the inner ride of the loop on the ninetern day and the patient allowed to get out of bed and aft in a chair. This is more advantageous and comfortable than atting with the limbs extended in hed as the abdomnal contents are less crowded. She accouraged to walk on the following day and on the twenty first the aslkworm-gut autures and on the twenty first the aslkworm-gut autures quently pulled upon. If they do not come away easily force is not used. The patient is en couraged to walk about and gentle traction is

again made on them in a day or two. The severing of the terminal fibers of the latisumus doral along their attachment to the erector spinze and the lumbar fascia and the transferring of the lumber portion of this muscle to the outer boundary of the wound permit of a complete exposure and easy access to the upper portion of the lumbar fascia or superior triangle. This temporary removal of the muscle from the direct line of approach to the kidney not only facilitates deep manipulation but affords an opportunity for the selection of the direction of the fascial incision. The latisamus doral is usually larger on the right aide than on the left, owing to the fact that most people are right handed. When this muscle is not well developed, considerable care must be used in severing its fibers near their lumbar attachment so as not to open the sheath of the erector spince nor cut the lumber fascia immediately below. The fibers of this muscle in the lumber region are usually attached in greater part to the sheath of the erector spina, but it occasionally happens that its lower one-half or more is attached to the lumbar fascia only thus leaving a considerable part of this fascia uncovered by muscle. When the lumbar fascia is incised in the general direction of the erector spins, as is commonly done, the nerves and blood-vessels which lie immediately below and which run nearly at right angles to the incision are necessarily subjected to great risk of injury but when the fascia is incised immediately below and parallel to the last rib we approach the deeper structures of the outer side of the last dorsal nerve. This nerve follows closely the lower border of the twelfth rib for a short distance, then changes its direction slightly Its average distance from the rib in the lumbar fascial region is about one centimeter. The nerve is easily located under the fascis on the inner side of the incision and close to its edge and as its divergence is in the general direction of the pelva a continuation of the incinion outward into the transversalis and internal oblique muscles can be made to any required extent without fear of injury to it unless there exists an abnormality If it is desired to enlarge the incision inward the lower border of the rib must be followed

During operation the perve is practically always within view and easily avoided when passing the slikworm-gut sutures through the muscles and when closing the fascial incision. Exceptions to this course of the nerve may be met with, that is, the nerve may follow closely the twelfth rib its entire length necessitating great care in avoiding it when enlarging the incision and when passing sutures through the outer portion of the wound. I have encountered this abnormality twice The importance of avoiding the perve cannot be overestimated, as injury to it is often responsible for painful sequelse. The last dorsal, the illohypogastric and the ilio-inguinal nerves are encountered in most methods of approach increasing thereby the chances of nerve injury Post-operative pain and diasthesia along the illohypogustric nerve in the gluteal region, pain in the outer side of the thigh and hyperesthesia along the course of the iliohypogastric nerve have been frequently observed following the technique of approach through the lumbar fascia at a right angle to the general direction of the nerves of that region and there fore constituting a serious objection to this method of approach. Since adopting the present technique of approach post-operative nerve symptoms have been materially lessened.

The only arteries of any aim encountered in this technique are sufficiently small to be controlled by forceps pressure and are encountered usually when in the lower angle of the wound as the aponeurotic or terminal fibers of the lattistimus dorst are severed and the other in the upper angle of the fascial incision when the incision is extended to involve the lower digitation of the serratus positiva inferior

On replacing the kidney the posterior portion of the fatty capacile is removed if any of it remains attached to the lumbar muscular area, as its presence there will interfere with the proposed. The remaining portion of the fatty capacile is forced anterior to the kidney and main tained there until the fibrous capacilar flap is anchored to the under surface of the lumbar fascia. The fat is in this way prevented from wedging between the kidney and the lumbar area.

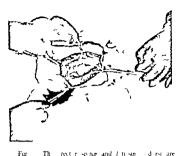

Fig. The restriction and fitting designs shown at the bottom in the cound. The lumba near-the latasumus dore are in the ear of tip at the period of the strength of the lumba near it is not in the countries. John freed from the lumbar is easily and time tried to the countries margin at the wound.

to which it is to be fixed. When the denuded posterior surface of the kidnes i in thi manner apposed to the aponeurotic covering, if the quadratus lumborum and union between them takes place there is established a condition of the kidnes closely approaching normal namely stability with limited mobility.

By following the technique herein described the possibility of injury to the last dorsal nerve and its blood vessels is eliminated unless their location is abnormal and even then by careful manipulation seriou injury can be a orded Opening into the peritoneal cavity i, impos ible excepting when the liver r pleen i prolapsed and mutaken the the Lidner. In passing the ustaining utures about the poles care hould be taken to disc ver and avoid the ureter and the renal vessel. In delivering the Lidney from the wound we sometimes encounter an accessory arters paling through the fatts capsule and entering the kidney u ually near one fit poles This is recognized fir t by the greater resistance it offer a compared t that offered by the tatty capsule alone and al) by its pulsation The artery hould be secured by a forcers before turther attempt is mail to deliver the Lidney With ordinary urgical care the delivery per hould entail no danger

It possesses the advantage of permitting a thorough preparation of the kidnes and allow a complete examination of the organ and upper

urmary trait and affir an easy approach through the pelvior the ureter for the removal that uhou to how implication be his vered

In replacing the kidnes that were perturn half a a rul ber turned in the It difficulty be met with it to unlik due to the intra abd minal taseia ifering in additional obstruction at the laver angle, the wound. To tailitate replace ment this taseia may be further increed or retracted. Unlik it is not necessary to graph the cut edges of the lassia with a torsepoint the angle and gently for the pile through the finest housing.

Though the anatomy at the lumbar region to tamiliar to every urgeon the tunctions 1 the structures about the kidney with respect to the support and mobility of the organ are vitin dipute. The kidney L afforded its chief protection from external influences by the pinal c lumn the great back muscles and the lower ribs Within their boundaries there i a well-defined to sa in which the kidney rest. This i was varies in depth with the ex and in different individual of the same sex. Any influence which restrict the tree motion of the upper abd minal and lumbar regions as for in tance tight lacing tind to force the kidney at of the firm and all text it to the depresing influence it fire from all v The toma is therefore an indirect fact r in the maintenance of position. The killnes has n ligament trictly peaking but i m) let 4 urr unded by a tring facial tructure. The tractal tructure r capsule i lut a part f

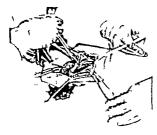

Fig. 3. The fascial mel-ion strended in hung in the lower angle, the internal oblique and trains evalls muscles

the great intra-abdominal fascial system which is so wonderfulls arranged as to render vital support to practically every add munal organ and out of which most of the so-called ligaments of the abdominal viscors are f rimed. The renal arteries and veins render no support while the kidnes is in normal position. These vessels support the kidney and restrict its mobility only when it is forced bevoud its normal range of motion which motion does not exceed in any direction, three centimeters.

The fascial capsule or perirenal fascia is composed of a posterior and anterior layer Suneriorally and outwardly these fascial layers are continuous inferiorally and inwardly they do not blend and can be easily separated by blunt dissection. Inwardly they surround the renal vessels as far as the spine, where the posterior layer terminates and is attached and the anterior layer blends with the corresponding layer of the opposite side. Inferiorally they surround the ureter and their failure to unite in this direction constitutes an essential weakness in the scheme of renal support. The posterior layer also called the retrorenal fascia, is intimately attached to the fibrous arches for the peops and quadratus lumborum to the twelfth rib in this immediate vicinity the first and second lumbar vertebras and the danhrasem. As the upper and outer portions of the anterior layer are continuous with the corresponding portions of the posterior laver and the posterior layer is fixed to stable points of the anatomy the stability of the anterior layer is greatly dependent upon the fixity of

I ig 4 The f tty apsole open kidney seen t the hot tom of the ound. (Photograph unsuccessfully retouched.)

the posterior layer con tituting a most important factor in renal apport.

Between the kidney and the fascial capsule there is a network of areolar tissue in the meshes of which is deposited fat constituting the tunical adiposa. This so-called fatty capsule renders support to the kidney to which it is attached only as it is in turn supported by the fascial capsule t which it is also attached. The fatty capsule renders support to the kidney only within the limits of the fascial capsule that is if the fascial capsule were detached from its fixe! points of support the kidney with its capsules would prolapse and be limited in descent or motion by the resistance of the renal vessels alone but if the fascial cansule remains fixed and the tunics adiposa be completely severed from its attachment to the kidney the kidney would then prolapse within the limits of the fascial capsule

Morris cites that in the infant the fatty capsule does not ensit and it is the peritoroum which is the chief agent giving facture to the kidney. The conclusion to be drawn here is that with or without the fatty capsule the peritoreum is an important factor in supporting the peritoric may be sufficiently for my mind the resistance afforded by the peritoneum per se and the support transfers the kidney in infant or adult is practically inconsiderable. The peritoroum is attached to the intra-abdominal fascar from which is formed the fascal capsule and its stability is dependent upon the stability of this fascal carpule.

Edebohl remarks that in the early operations of nephropex, the idea dominated that the kidney ought to be anchored as high up as possible

I is The kilms left red and ease of the fatt up-ula which has been for ed into the und introdis. (The on stands for each the

under the ribs. The fact was not sufficiently rec agrized and appreciated that it is the mobility of the kidney v hich gives rise to the symptoms and that the latter will be perfectly relieved by anchorage of the loos organ even at some distance from its normal babitat. The attempt to realize the ideal inspired the practice of anchoring more or less of the lower end of the kilney only leaving the untouched pole to project upward beneath the ribs. This lead in many cases to either anteversion of the upper pale or to the crowding down of the killn's and often resulting in the return of the old symptoms states that the kidney cannot be fixed in its normal position and should be fixed squarely in the loin. The middle part tills the lumbar spaces the upper part projecting as far upward beneath the rib as the lower pole reaches downward below the level of the crest of the ilium

The practical result of the technique that I follow as well as experimentation upon the cardaver have demonstrated that the kidney can be surgical means be placed in the immediate region of its normal habitat the only exception being when the liver or spleen are also consider ably prolapsed and enlarged for its occupying the kidney region they crowd the organ and may revent it from assuming its normal position With no obstruction in the upper lumbar region the elevation of the entire organ is ensured by tying the suture energing the lower pole first. The tring of the upper suture next ensures the position of the upper pole and the mobility of the crygan.

When the heath of the jun fratus lumborum

The notes the second to the second that posterior in rest the kalmer etc. If a trom [is to pule a lit in lithin new mit mit in the hilum.

mened it entire extent and the muscular tibrou layer laid bare a advised by I lebobl it is difficult to prevent injury to the nerves and blood bessel of the real not rether par immediately in front of the muscle fixation of the kidney to the muscle causes an abnormal relation ship and every metion of the muscle imparts motion to the kidney and every force acting on the Lithey must not correspondingly on the muscle The function of the nerves and vessels are likewise frequently interfered with his such intimate and abnormal fixation, but union of the kulne to the fascial and aponeurotic tructures covering the quadratus lumborum would in no way interfere with functioning of the muscle nerves or blood vessels The only preparation of the muscle area in the technique which I advocated is the removal of the retrorenal fat if any remain attached to this area

According to Edebohl the broader the surface the stronger will be the an for union He in common with all others aimed chorage to fix the outer or convex surface of the kidney to the antenor plane of the quadratus lumborum In so doing he made an extensive denudation of the kidney surface but this stripping back of the capsule beyond the limits of the convex surface does not increase the area to be approved for tixation In width this surface i usually no more than two and one half centimeters and because of its considerable convexity its middle one-third only can be well apposed to the flat surface of the muscle. The posterior surface of the kidney presents the least convents and greatest expanse for apposition and if the question of permanent anchorage resolves itself into the question of the extent of the urfaces at posed there is left no room for argument as to which surface of the ladney is the surface of chance

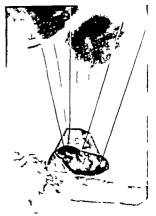

Another eljection to fixing the kidnes in its

I to f . Three V . O chromac cattent sut no penetr it the margin of the freed portion of the librou ap-ale Mee the kidney is replaced these suturn or used to anchor this fibrous flap it the unds surface of the lumba f .cda, where it act as should to perseen the f it from entering bet even the kidne, and the quader to-furnisement

con ex surface is that when so fixed the hilum is forced forward and out of its normal and anatomical relationship H wever when the posterior surface which is sightly conv v is apposed to the conca it of the lumbar rank n the hilum is directed inward and it anat mical relationship restored Resting thus posterior surface the kidney occur as les spa e anteroposteriorly than when fixed by to sufer surface, and assuming thus a protected position in the lumber fossa according to Nature plan escapes force from abo e a when a coin tluced in the palm of the hand escapes the influence of brush passed over it

The principles of nephropexy a lyocated by Billington are open to several objections. The suspension is made in part through a flap of the fibrous capsule stripped from the upper half of the convex and posterior surface. Additional support is rendered by two Brodel sustaining autures inserted in the attached fibrous capsule covering the lower one half of the convex surface The fibrous flap the base of which is attached to and crosses the center of the convex surface is passed up and out between the eleventh and the twelfth ribs and attached to the lips of the fascial incision. The Brodel sutures are tied first being inserted in the attached portion of the fibrous capsule on the lower half of the convex sur face direct and fix this area to the posterior wall. The position occupied by the kidney when

lig 4 That sort among silk orm-gut sutures re here show marching the kidnes also the three fibrous aponk turn

so u pended is on a lin external to the outer margin of the rect r spina and the middle of the t border is on a level with the twelfth rib while the hilum is directed forward. This post tion f the lather is not normal and the organ becomes to a dangerous degree exposed to force from above. In Billington a technique no prousion is made to support or even limit the motion f the upper pole so that this pole is free to move in whatever direction influenced. Under these circumstances a displacement of the upper pole always possible when omiting or coughing are severe and persi tent. The organ is therefore hable to topple over or antevert and produce a twisting of its pedicle. Also when the liver is enlarged or is prolapsed much below the twelfth rib it is practically impossible to adopt Billing ton s technique.

The technique ad ocated by Longvear fails also to ensure the normal replacement of the kidney and as the position of its upper pole is not

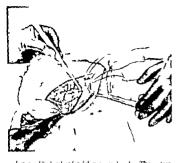

Fig. 6. The I mbur fuscial a is in losed. The tain ing silk irragint sutures hat pen trated the muscles and shin and ire seen emerging near the piper ingle of this shin in is in. The Cretouched but unsuit \(\text{tr}(t) \).

ensured the kidney may likewise antevert and produce a twisting of its pedicle Longvear s technique possesses one possible advantage and that only when the anterior layer of the fascial causule has been considerably stretched by the prolapsed kidney his technique fixes the cellular structure termed by him a renocolic heament which connect the lower anterior surface of the kulney with the anterior layer of the fascial capsule to whe h on its peritoneal side is usually attached the colon and in so doing may elevate to some extent the colon. But the cellular struct. ure of the fatty capsule is a structure of little resistance and the permanency of the apposition may be considered doubtful if it is dependent upon this structure. The area of the anterior layer of the fascial causule to which the colon is attached is located near the spine and as this layer of fascial capsule blends with the corresponding layer of the opposite side and is attached to the us use of the spine it is rendered more stable than the middle portion. In prolapse of the kidnes it is usually the middle portion of the anterior fascial layer which yields. Cases are not uncommon however where th prolapsed organ follows the line of fascial cleavag in the direction of the ureter where the failure of the lavers to fuse constitutes a weakness in Nature's scheme of Lidney support

When the kidney is fixed by the technique which I advocate the constant pressure on the anterior layer of the fascial capsule is reheved. The released latty capsule placed anteriorly must

Fig. The wind losed and the tilk im gut sustalling uture tail or air all of ind if im gauze

again attach itself somewhere and can attach itself nowhere but to the stable kidney. The overstritched fascial capsule releved of the weight of the kidney returns to its normal condition and position. If however it is considered necessary or desirable to fix the lower cellular tissues which are indirectly connected to the colon it can be accomplished during the operation by passing one or more sutures through it and anchoring them to the lumbar fascia when closing the taskial incresion.

SUTURE MATERIAL

I prefer the use of the silkworm gut as a sustaining suture to chromic gut or kangaroo tendon because the power is constant while that of the absorbable diminishes in strength daily. With the use of the silkworm gut the maintenance of the kidnes where placed is ensured until sufficient time has elapsed for strong union of the surfaces apposed. With the use of the absorbable materials there is no certainty of this apposition remaining when force is exerted from above, such as may be caused by deep breathing, persistent coughing or vomiting.

The objection has been made to silkworm-gut that it is likely to cut the lidney surface. This objection is only theoretical as in my experience such has never occurred. The sustaining sutures do not touch the kidney proper it being protected by the attached portion of the fibrous capsule on its entire surface. It is necessary that the silkworm gut sutures be carefully selected and that they be of large lize and smooth as points if

108

roughness make their removal difficult. Such an experience I have met with twice in each instance great care and patience had to be exerted. In one of these cases more than a week of gentle traction daily was required and on removal of the gut it was discovered that extensive corrosion at several points had taken place. The black dved is not desirable as it is frable. Plain or vegetable dyed is to be preferred.

The arguments advanced in favor of silkworm gut apply equally to silver wire the latter possesses the additional advantage, however of never becoming rough. The chief objections to its use are that it is not always conveniently obtained and that if the loop has in it a kmk, the removal of the suture may be difficult and painful.

The absorbable sutures are less objectionable as sustaining sutures if they are brought out of the body and tied over a roll of iodoform gauge as a done with the non-absorbable. By this technique the burying of the knot in the tissue is avoided Nature is usually capable of contending with these knots but she sometimes isils.

DRAINAGE

Drainage is never necessary excepting perhaps where a stone is removed at the time of nephropexy If a stone be removed from an musion in the pelves of the ureter the direction of the drain should be from the area between the pelvis of the ureter and the muscles of the back along the lower pole and through the lower angle of the lumbar fascial incision. It should then penetrate the fibers of the latisumus dorsi immediately above and pass out through the corresponding opening in the skin. If the stone be removed through an incusion in the cortex, the drain is Figurals afficuous gut has been tried but without intiniention, as the tennes become entracted in its fibers and marker its removal deferret

in the same direction as described, but leads from the convex border only When the cortex is cut in removing a stone, the sutures encircling the kidney assist materially in apposing the cut surfaces and in checking homorrhage.

In both pyelotomy and nephrotomy nephrovery should at the same time be done. This can be best accomplished by the technique here advocated because in so doing the kidney is suspended at its greatest possible elevation and consequently thorough drainage is ensured to the distended pelvis or pus cavities.

- This approach to the kidney necessitates the least injury to the tissues encountered and facilitates deep manipulation
- 2 In closing the wound only a minimum amount of the simplest suture material is required and the replacement of the tissues is absolutely anatomical
- 3 The kidney area exposed for attachment is the most extensive surface available and so altunted as to permit the kidney being anchored in normal anatomical relationship
- 4. The sustaining sutures encircling both poles ensure immobility until firm union has taken place and their high placement in the tissues of the back ensures a practically normal position of the OFCAR

A METHOD FOR PREVENTING AND CONTROLLING HÆMORRHACI FOLLOWING PROSESTECTOMS

By I. H. COOK, M.D. BILLER INDIA

ROST ITECTOMY may not be followed by severe hæmorrhage bleeding may be slight or severe and readily controlled by one of the various procedures ordinarily applied. But in some instances it may be alarming especially in the aged when the loss of blood and the accompanying shock greatly lessen the chan es In addition to the means that have for recovery been suggested and already applied the following device seems to me to possess advantages that would be of value when hæmorrhage becomes severe or difficult to control

A catheter of good size is passed into the blad der and drawn out through the opening at the tundus a strip of gauge about one and one half inches in width and of sufficient length as may be required to make a pack approximating the size of space to be packed is wrapped around and above the opening of the catheter by two or three titches coming out at the side of the catheter over the gauge and tied the hr t knot being drawn down snught to the gauze. Before tying the second knot a thread of sufficient length to be drawn out of the bladder wound along with the end of gauze strip is placed over the first kn t when the second knot is ued. The thread

making the tie is then cut close to the knut. or three such threads are placed each long thread and strip of gauze is held when the catheter with the ring of gauze pack is drawn into the blad ler dana to the bleeding area sufficient traction being made to secure coaptation of the denuded surfaces thus obliterating the space x cupied by the prostate. When the danger from hæmor rhage has subsided traction is made upon each thread thereby releasing the second knot Traction upon the protruding end of the gauze releases the first knot and unwinds it from the catheter permitting its easy withdrawal from the bladder. The drainage or irrigating tube is placed to be removed when desired

The gauze pack applied in the manner de scribed not only serves in controlling and prevent ing dang rous harmorrhage but also serves to replace the torn and overlapping bladder wall holding the denuded surfaces in place an aid to early union of the parts s-partted by the operation rendering unnecessary the frequent hot water irrigation used by some operators a means of controlling hiemorrhage that is not only pain ful to the patient but adds to shock from frequent

PAINT BRUSH DRAINAGE TUBE

BI A MERRILL MILLER M.D. FACS DAVILLE LLINOIS

OR some time past the split rubber tube has found favor for use in cases requiring dramage

The objection to its use in the abdominal cax ity is the danger of necrosis of soft tissues by the hard unvielding end. To overcome this objection and retain the advantage of the tube. I use a tube splitting the entire circumference an inch or more in its long axis. The small rubber

terminals thus made will not cause pressure no crosss and will readily adapt themselves to chang ing positions of the abdominal viscers (see illus tration)

BOOK REVIEWS

A CRITIQUE OF NEW BOOKS IN SURGERY

B MAJOR G SEELIG M D S LOUIS

THERE is something subtly deadening in reading with the fixed purpose of criticisingsomething that is not categorically different from the state of mind f the moduste as she surveys the new spring styles. If one cann t successfully lose the thought that he is a critic, he finds blusself inevitably snared in a mase f data, which though fotted down purely for purposes of criticism confuses his sense of appreciation and clear reasoning This is particularly tru of medical books. Medical theory and practice is in a state of constant flux there is so very little that may be expressed in warrantably ex cotted fashion, and by contrast so very much that is promulgated with the seal of authority affixed that one subconsciously finds himself holding his mind open to mere details worthy or unworthy upon which to rest his criticism.

On the other hand, if one reads for the simple oy! earling unmindful of opinions that may be crystallizing in his own mind as he rends, be finds that each volume makes a totallty of appeal to his judgment. He sees and feels what he otherwise would have failed to see and feel. Good reading, like good pelinting, should be done with the thought

of perspective and proportion always in mind. There is central kles of purpose in practically every volume published. The art of the critic lies in furnishing sane comment on this purpose, or in pointing out the failure or success of the author in making his purpose clear Of course in doing this, details must neither be elded nor lost sight of, the reviewer should been in mind merely that if he dissociates himself from the large purpose of the book, and centers his critical attention unduly on details be will too often find himself not seeing the forest for the trees.

Let us go thro gh the books of the month with the n tion in mind of the impelling motive that is responsible for each volume. Whatever there may be said regarding the value of this type of critique no one may say that it is lacking in interest

THIS volume on indeptable Bes S get a filturestee most admirably exactly what we mean by the phrase central idea of purpose. One does not need the statement in the pref ce of the book t convince him that the authors have had their interest awakened from three different than the statement of the property of the second of th

directions experimental bibliographs and linical. There are n con rete tatements in the text emphasizing the fact but one k ow nevertheless, that the thors felt the inner drive to id in clarifying a urgical topic that is just now in process of evolution 5 h purpose is worth, and it is gratifying the sable t more that across publishment has kept page fairly well with purpose.

The book does of differ markedly from its sister volum suffer almost synchronously by Ubec and recently reviewed in these columns. A careful survey shows that in put of a different arrangement of chapt beads, the sam subjects re treated in the time of the sum of t

clear crisp summary of the fundamental facts. It is interesting to note that the I docations for bon grafting formshed by D vison and Smith stally looset it. In letter with the Indications settled by Ubec. One is also struck by the fact that these uibon have seen the wisdom of doing what Albee f Iled to do namely appending what seems to be a very foll and accur it bibliographs.

Anyone wh has followed this new chapter of bone surgery clorely mindful of the great diversity of opinion so therebie since the publication of X cesen book, G exit B Ben will naturally hexiste to take shifes with or against the authors on any desulted question. The thing of significance and interest is that the purpose back of the boar importance from the Gutenite is well as from the purpose that of the board importance from the Gutenite is well as from the purpose the first properties of the purpose of the first properties of the surgery of the following the first properties of the first properties

THIS next book by Dr Crile has i some inexplicable wy reached the reviewer's sanct m bout one yea late. The delay is in a local Amount of Dr. Brand Barbar and London W B water on paray

sense fortuitous for had the book reached us on whedule time we would have felt obliged to para phrase the doctrine of anord association comment in its scientific basis dilate upon the nealness and itrength of Crile's methods in short fuse the new doctrine in the crueble of criticism. Now for lumitely all this has been done for us. It is fretty safe to assume that those who do not feel what William James used to call the sense of personal warmth of knowledg of the anous issuciation theory do not read \$\text{K}_1 \text{En}_1 \text{K}_1 \text{N}_1 \text{N}_1 \text{N}_2 \text{N}_2 \text{N}_2 \text{N}_1 \text{N}_2 \text{N}_

judicious at is necessary to say at the outset that we feel that the recent severe criti ism of anoct association by Carlson even though it took on somewhat the form of a polemic was in good part justified. This is unfortunate and equally unfortunate as the fact that many of Cril a conclusions do not flow from well-constructed a flogisms but

seem to be revelational

If one dismisses for the time being all such broad generalizations as the above he inacordably centers on the drive back of the work the enthusiastic, determined effort to popularize a doctrine. And however much one may take usu with the so-called pure science of the nork or how ever sprittedly he may cavil at the all too comprehensiveness of Criles inductions he must nevertheless feel the weight of sin are flort typesented by the large amount of experimental data

collected over a long period of time

The presentation of this mass of experim neal data marks only one half of the purpose of the book-it stands as the academic purpose. Mu h more important are the advantages that have accrued to surgery. These latter results onstitute the practical norkaday purpose of the Extrine Beyond all question of doubt. Crile has ingrained a spirit of surgical g ntl ness in the consciousness of countless surgeons Careful selection of operative material gentleness of manner deliberate and thoughtful precision of a t closely fusion of individual efforts-these are things that have resulted directly from Crite's magnetic n rls written and spoken and I for one am content to let such thing up the balan e against the load of somewhat faults logic. In other words I am inclined to pass over the conflict of testimony and to experience a deep sense of gratitude for what the doctrine of anoci-casociation has done for surgery from the crass practical point of view

In this volume Smithies has collected the largest amount of clinical data o ering the greatest number of intensively studied stomach cancers

that I have ever seen grouped between two covers. In reality the book "omes under the head of monographs but bulk form thoroughness and "eaith of illustrations force one to group it under the head of treatuses".

The plan of the book excellent throughout rests on a carefully developed chapter division of twelve parts. Each chapter in its turn is based upon the personal expenence of the author and then rounded out by a critical selection from literature of data bearing on the various important topics discussed. It is impossible to overestimate the value of the method of exposition. For example in Chapter VIII on 6 actin Cancer in the Young Smithles not only analyzes in minute Jetail eigh teen such asset of arcinoma studied by him but also furnishes his reader with the references necessary for a broad on epiton of this mast interesting though limit of topic. Welch Osler McCrae and Dock)

Chapter I C neral Distribution and Etiology furnishes nothing n w but m rely presents in rather extended fa hi n mu h valuable data collected from viri us a credited sources. Chapter II on Murbid Anatomy is notable chiefly for the large amount of pathological material, and the care with hich it has been studied Excellent and painstaking as has been the work of MacCarty it hardly justifies Smithies statement that to it ne ne pra ti ally all our useful knowledge regard ing the early histologic changes which are assoat d with the de clopment of gasini anter. The notable point in Chapter III Symptomatology is the radical and yet rational (though we must concede Utopian) hupe expressed by the author that the early diagnosis of cancer f the stomach must be made mu rescopically from a lat of freshly This chapter is particularly full removed tissue eml racing as it does quite a number of illustrative as histories Charter IV deals with physical signs under the questionable title of Physical In this chapter Smithies very Unormalities wisels dilutes upon those signs in enumerator seven of them) which determine the inoperability of gastric malignant neoplasms Chapters \ \I and \II deal in order with the clinical microscopy of gastrointestinal function roentgen examination and blood changes in gastric arrinoma. That portion devoted to roentg n examination is only fairly well illustrated the plates are by no means as good as the recently published ones in the work of George and Leonard It is necessary to emphasize this fact because a poor reproduction of an X ray plate is worse than useless. Chapter VIII the Signif. i ance of Gastric Ulcer with Respect to Gastric Can or suffers somewhat by reason of its highly statistical character. We should have preferred a more condensed and concentrated arrangement of the statistics followed by a more distin-tly personal statement by the autho of his wn interpretation of the figures. Chapter \ Differential Diagnosis is the weakest chapter of the book

support of this criticism is necessary than the mere mention that Smithies does not even suggest pernicious anemia or tuberculosis in any of his differentiations. If one calls to mind the chapter on differential diagnosis in Schmidt's book on T more of the Abdominal Viscera he will at once appreciate how far short Smithles has fallen. The final chapter on the non-surgical treatment of can cer of the stomach is admirably done and con stitutes a most valuable part of the volume. It is unfortunate that Smithles, in describing the tech nique of transfusion in inoperable cases, describes the method as the Percy-Cook method. credit should go to Kimpton to whom t properly belongs. The chapter on the surgery of gastric cancer written by Dr Ochaner is adequate and particularly well illustrated. One misses, with regret, any mention of the recently proposed Polya method of gastric resection. C mment on this operation by Ochaner would have been par ticularly valuable

On the whole the book fulfills its purpose well in demonstrating the value of an intensive, well correlated study of clinical material. The only thing lacking a just a bit more of Smithits himself for the sake of color and interest. A strongly personal note dis conviction as well as sail and spice to a book. On pages 67 and 68 the a thor train in rightcom wrath against the fox troit

bumy hig correts et al and states in most unequivocal terms his own ideas regarding what constitutes proper physical examination. We should have enjoyed a thicker tudding of the volume with this same style of writing THE new third edition of Edwards Practic of Medicine has been reviewed for us by D Mandel in the following words

"The book is practically rewritten and rearrange to conform with the more recent classification diseases. Much new matter has been addeed Expecially commendable is the space devoted to diagnosis. The differential diagnosis correling diseases of the heart, liber kilonys, bloc states, etc. are complete and practical and should be of value to the student and teacher. Surgioi indications in border line cases, statistics, medicing and surgical, and the extensive bibliography enhance the value of this new work and create a specia appeal to the surgeon.

Treatment is outlined in great detail. This particularly true in the treatment of cardid insufficiency syphilis and tuberculosis. The dietetic treatment of nephritis and diabetes as proa hes in completeness that which we might expect in a work on dietetics. The discussion of the more commonly used drugs is another unique of the more commonly used drugs is another unique.

and laudable feature of the volume.

In this edition as in the two previous edition
the author has succeeded in subordinating the
theoretical and eliminating the obsolete, thereb
gwag us a Practice which is complete practice
and up-to-date an ideal text-book for students,
necessity! the general practitioner and a valuable
addition to the library of the teacher

ADVISORY COMMITTEE OF CIVILIAN PHYSICIANS AND SURGEONS ON MEDICAL PREPAREDVESS

T NFORWALLY it was brought to the at tention of a number of civilian physicians that a consulting committee on medical preparedness would be desirable. This resulted in a suggestion that the presidents of the Ameri can Medical Association the American Sur gical Association the Congress of American I hysicians and Surgeons the Clinical Congress of Surgeons of North America and the American College of Surgeons should jointly appoint an ad interim committee which could co-operate in developing the civilian and reserve medical resources of the country to the highest point of efficiency. As a result of these suggestions the following committee was appointed in the manner indicated the presidents of the various societies acting as members of the committee

William J Mayo Chairman Rochester Minn Frank F Simpson Secretary Pittsburgh Pa

Frank Billings Chicago John F Binnie Kansas City Mo Joseph C Bloodgood, Baltimore

George E Brewer New York City George W Crile Cleveland J M T Finney Baltimore Charles L Gibson New York City Robert G LeConte I Iuladelphia

Richard P Strong Cambridge Mass William S Thaver Baltimore Albert Vander Veer Albany N V

Victor C Vaughan Ann Arbor Mich This Committee met in Chicago for organiza tion on April 14. Dr. William J. Miayo of Rochester Minn was elected Chairman of the Committee Dr Frank F Simpson of Pittsburgh

Secretary and an Executive Committee chosen as follows

George E Brewer
George W Crile
J M T Finney
Robert G LeConte
Fred B Lund

William J Mavo Franklin H Martin Frank F Simpson William S Thaver Albert Vander Vecr

On April 20 the Executive Committee met in Washington and presented in person to I resident

Wilson the following memorandum

Washins for D.C. April 20 1916. Dear Mr. President—We the undersigned acting as a committee on behalf of four national societies to wit the American Niedhalf Visocia from the Congress of American Insections of Surgeon to the Chinical Congres of Surgeons of Surgeons of Surgeons representing an aggregate membership of 60000 medical men have the honor respectfully to present our greeting and to tender to the Federal Government our services toward the medical welfare of the Amys and Navybeing impelled so to do by the following considerations

1 In times of peace as well as in times of war the medical profession as above represented holds itself in rendiness out of a spirit of patriotism and of co-operation to serve the best interests of the Federal Covernment.

2 The European war especially during its first six months demonstrated a greater need both of medical supplies and of more efficient organization of medical resources, in connection with military and naval activities than was formerly deemed necessary or adequate.

3 Every soldier and sailor in the service of the Federal Government is entitled at all times to protection in sanitary matters and to pro-

ticient medical and surgical care

Prompted therefore by these considerations the medical profession as above represented respectfully offers its services toward the well being of the army and navy departments. Among the scruces which at this time the above named organizations specifically tender their co-operation in conjunction with existing facilities of the Army and Navy for such purposes are

r To establish through their respective mem bership and their affiliations with local medical societies of the states and territories an or ganization that would be in a position to make a comprehensive survey of the medical resources of the country

z To make a complete invoice of such resources available in peace and in the emergency of war This invoice would include not only the names of men available for field or home duty who are trained in the specialties of medicine surgery and sanitation but it would also include the extensive equipment under the control of these men such as hospital facilities and lists of trained nurses.

3 To aid in the public health service in sanitation, quarantine, and hygiene of the troops to aid in the inspection of camps and posts to analyze water sources and supply systems to study effects of climates, exposure, diet etc all designed for the welfare of the individuals enlisted in the Army and Navy Departments

The medical profession as above represented respectfully submits that thorough organization of the civilian and reserve medical resources f the country are of primary importance in the proper preparedness of the country It does n t however here and now offer or imply any rec ommendation as to the national policy for pr paredness beyond adequate sanitary medical and surment protection of those who may be enlisted in the army and navy d partments Respectfully submitted

PLANS FOR THE PHILADELPHIA MEETING

N the following pages is presented a preluminary program of the evening meetings to be held during the week of the Chincal Congress of Surgeons in Philadelphia. All of these meetings with the exception of the public meeting on Friday evening are to be held in the Ball Room of the Bellevue Stratford On Friday evening in Witherspoon Hall located only a short distance from the Bellevue Stratford, there will be an open session to which the public will be invited. Questions of great interest to the public will be discussed by men who can speak with authority concerning the problems presented On three e rennes of the week there will be sepa rate meetings for the section on surgery of the eve ear nose and throat the program for which will be published in an early issue. These meet ings will also be held at the Bellevue Stratford.

It is evident from the number of registrations already received at the office of the Secretary General that the limit of member ship fixed for the Philadelphia session will be reached within a short time. Bearing in mind that several hundred surgeons who wished to attend the Boston meeting last October were disappointed because their registrations were received too late it is urged upon those surgeons who wish to attend the Philadelphia meeting but who have not sent in their registrations that application should be made immediately to the Secretary General Dr. Franklin H. Martin. 30 N. Michigan. Ave. Chicago Illinois When the required number of registrations has been received no further applications can be accepted.

A careful survey of the operating amplitheatres lecture rooms and laboratories of the several medical schools and hospitals in Philadelphia as to their capacity for accommodating viaiting surgeons, has been made and the limit of attendance based upon this survey. The popularity of these clinical meetings has become or great that the plan of limiting the attendance and requiring advance registration was decided upon to prevent overcrowding. This plan assures accommodations at the clinics for all who hold membership cards and has worked satisfactorily at the two previous meetings, in London in 1914 and in Boston in 1915.

THE CLINICAL PROGRAM

The schedule of clinks and demonstrations to be given by the clinicans of Philadelphis during the week of October 23d as published in these pages is a tentative one and is to be amplified and corrected from month to month as the work of the Committee on Arrangements progresses, so that the final program will properly represent the clinical work of the Philadelphis surgeous. The Committee on Arrangements has planned for a complete showing of Philadelphis a clinical facilities in every department of surgery in cluding synecology obstetrics, genuto-urmany surgery orthopedics, surgery of the eye, ear nose, and throat, together with many demonstrations on borderline subject.

DEMERSHIP—REGISTRATION FEE

The Constitution of the Congress provides that all subscribers to the official journal. Surenzy Gymerology And Obstrations are members of the Congress and that such other legally qualified practitioners as are in good standing in their own communities may become members upon regularing at an annual meeting.

The constitution also provides that a registration for shall be required of each member attending an annual meeting, there being no annual dues for members of the Congress. The registration fees provide funds to meet the expense of preparing for and conducting the

annual meetings so that no financial burden is imposed upon members of the profession in the dty entertaining the Congress.

HEADQUARTERS

Headquarters will be established at the Belle vue-Stratford where the Ball Room, Groen Room, and adjacent foyers and smaller rooms have been reserved for the use of the Congress. These rooms are located on the second floor of the hotel and provide ample space for registration rooms and ticket bureau, bulletin boards, etc. the Ball Room being used for the evening meetings.

Room being used for the evening meetings. Headquarters will be open on the afternoom of Saturday October 11st, and on Sunday the 21d, for the registration of members. The program of clinics and demonstrations for Monday will be bulletined on Saturday afternoon, and on each afternoon, begunning on Monday the complete program for the next day's clinics will be posted on bulletin boards in headquarters. A printed program will be issued each morning and special tickets for all clinics and demonstrations will be issued to members at 8 a.m. each day

SPECIAL TICKETS

The use of special teckets at previous sessions as fully demonstrated the efficacy of this method of providing for the distribution of members among the various clinics. To prevent over crowding, tickets for any clinic or demonstration are limited in number to the actual capacity of the room in which the clinic or demonstration is to be given. These special teckets will be fisued at 8 o clock each morning for the clinics and demonstrations to be held that day a complete clinical schedule having been posted on the bulletin board on the afternoon of the preceding day and a printed schedule of the clinics distributed early each morning

PRELIMINARY PROGRAM OF EVENING SESSIONS

GLNERAL SURGICAL DIVISION-In the Ball Room of the Bellevue-Stratford at 8 p m

Presidential Meeting Monda i October 3

Address of Welcome ROBERT CLECUTE M.D. Philadelphia, Chairman of Committee on Arrangements. Charles H. Mayo. M.D. Rochester Minn. Address of returning president. Inauguration of President Feed Bares Lund. M.D. Boston, and Vice Presidents Jaspie Halpenny M.D.

Winnipeg and S. M. D. CLARK M.D. New Orleans.

Presidential address by Fred Barus Lund. M.D. Boston. The Indications of Cholecystectomy.

J M T FINNEY M D Baltimore Drainage of the Gall Bladder CHARLES H. MAYO M D. Rochester Minn. Cholecystostomy vs. Cholecystectomy

Discussion J C DaCosta M D Philadelphia, and John B Deaver M D Philadelphia.

Tuesday October A

DIAN LE 15 M D Chicago Fat and Fascia Transplantation.
Discussion Frincis T Struar M D Philadelphia.
C A PORTER M.D Boston Surgery of the Peripheral Nerves.

Discussion Charges H Frazier, M.D. Philadelphia and John H. Gibbo : M.D. Philadelphia.

Il ednesday October 25

J BENTLEY SQUIER M D New York City Kidney Surgery
WULLIAM, F BEAASCH M D Rochester Minn Recent Methods in Kidney Diagnosis.
BEAASTORD LEWIS M D St. Louis Diagnosis of Ureter Diseases with Their Surgery
J T Geraghty M D Baltumore Diseases of the Bladder
EDWIN BEER, M D New York City Treatment of Neoplasms by the High Frequency Current or Ful
guaration.

Discussion EDV ARD MARTIN M.D. Philadelphia.

Thursday October 26

THOMAS S CULLEN M.B Baltimore Methods of Draining Where Polvic Infections Exist.

J WHITEHOR WILLIAMS, M.D. Baltimore The Abuse of Censurean Section.

Discussion Edward P Davis, M.D. Philadelphia.

Discussion EDWARD P DAVIS, MD Philadelphia.

GRORGE G WARD JR. MD New York City Treatment of Inaccessible Vesico-vaginal Flatule:
Discussion Jours G CLARE, MD Philadelphia.

C. JETT MILLER, M.D. New Orleans Surgical Treatment of Puerperal Pyemia.

Discussion Barrow C Hirsy M.D Philadelphia.

THOMAS J. WATKINS M.D., Chicago Cystocele and Prolapse Discussion Brooks M. Anssach, M.D. Phil delphia.

Friday October 27

WILLY MEYER, M.D. New York City Cancer of the Breast.
ULLIAM J. MAYO. M.D. Rochester Minn. Cancer of the Stomach

Discussion Frederick W Parhau, M.D. New Orleans.

Groupe F. Armetrong M.D. Montrel Canada, Canada ith Large I

George E Armstrong M.D. Montreal Canada Cancer i th Large Bowel
Discussion Student McGutze, M.D. Richmond, a d E. Wyllys Ambrews M.D. Chicago.

HOWARD A. KELLY M.D. Baltimore Treatment of Cancer by R dium.

JAMES T. CASE, M.D. Battle Creek, Mich. Treatment of Cancer by X ray

Discussion George E. Prainter, M.D. Philadelphia.

Public Meeting Friday October 27 sn Il überspoon Hall at 8 p.m.

Under combined auspices of the Philadelphia Cou ty Medical Society the Department of Public Hellis and Charities, and the Chaical Congress of Surgeons of North America, Westron A. Pricz M.D. Cleveland Care of the Teeth (Illustrated by lantern and cinematograph.) JOSEPH C. Bloodgood M.D. Bultimore Diagnoss of Cancer

ROBERT W LOVETT M D Boston Description and Illustration of C rable Deformities and the Importance of Their Prooct Treatment.

EDITORIAL ANNOUNCEMENT

From time to time in the history of clinical medicine certain questions come up for intensive discussions appear to be settled temporarily and subside into quescence only to reappear later as a subject again for forensic debate or laboratory research. Such a theme is that which has recently added considerably to the literature of neurology and gynecology. The relation between gynecological and neurological conditions has been recognized since the earliest days of medical knowledge. It has aroused the keenest discussion at various periods during past generations. Following the claims of Bossi a few years ago fresh interest in this subject was aroused. Today the close study given the ducties glands appears to reveal a closer relationship and to explain this relationship in some degree It is, therefore timely that a critical review of this abundant literature should be offered to our readers and the International Abstract of Surgery takes pleasure in announcing that Dr Richard R. Smith has prepared such a paper to appear in the July issue.

Other collective reviews to be published during the next few months are Mechanism of Fractures EMPLET REXPORD M.D. San Francisco. Tuberculods of the Genito-Urinary Tract I H. CUMMINGHAM, IR. JULY 1016

COLLECTIVE REVIEW

THE VERMIFORM APPENDIX

A RÉSUMÉ OF THE LITERATURE

BY W FRANK FOWLER, M.D. ROCHESTER, NEW YORK

THE literature pertaining to the appendix has been extremely illuminating and in many instances conclusive during the past year. It is regrettable that a paper of this character cannot include all the excellent articles which were read in its preparation. The writer considers this compilation amply justified by the statistics of Murphy herein quoted.

ANATOUS

Recent embryologic studies of folds, bands and kinks have again demonstrated that various malpositions of the appendix are dependent upon partial or non rotation of the gut. Schrup (1) reports a case of this character which presented the usual symptoms of appendicuts and cystic ovaries. At operation the cystic ovaries were found in the ovarian region but there was no appendix crecum or ascending colon in the nor mal position. The jejunum occupied the right half of the abdomen The cacum was located behind the sigmoid. The appendix was long and congested There were no adhesions mesocolon was apparently attached at the left side of the spinal column. The stomach heart and liver were in normal positions. A review of the literature convinces Schrup that complete transposition of the viscera is more common than the type which he reports. The pre-operative location of the heart on the right side would suggest the diagnosis in complete transposition. In childhood non-rotation of the colon accounts for unusual appendix positions.

Corner (2) says Clinically it is frequent to find in children that the execum and appendix have not reached the line fossa, but have been delayed in their descent or become situated in the umbilical region. It is unusual for the left side of the abdomen or the pelvis to be reached. Appendicitis in the young is commonly atypical and it is necessary to rely on the generality that acute abdominal disease in children is probably appendicitis. Other causes of malposition of the appendix in the adult are an abnormally long mesocolon and an unusually long appendix which may reach to the left side.

Palamountain (3) reports a case of another type. His patient was a married woman, aged 18 a nullipara who had had irregular menstruation for the past year. She was awakened by a sudden severe colicky pain in the midabdomen which continued all night and was accompanied by vomiting. The pain was localized in the left iliac region and continued all the next day with occasional vomiting (aster oil and hot applica tions did not relieve the name. The next day she was driven to town Examination revealed a medium sized woman in severe pain. She leaned to the left side and Lept the left thigh flexed Menstruation had been delayed two days. Her temperature was 99 5 pulse 120 The abdomen was tympanitic and extremely tender over the left side percussion was almost unbearable muscle spasm was pronounced There was constant pain over the left lor er abdomen uterus was slightly enlarged and softened

cerv was soft. There was some pain in the left adnexil regon, and there was a suspticion of a mass in the left side. A tentative diagnosts of tubal pregnancy was made. Operation was refused until the next day when pain and fever had increased. Operation was performed fifty eight hours after the onset. It was found that the signoid was on the right side the ascending colon and illum and a gangrenous appendix were on the left side. Perthoutist was present. Later examination located the liver on the left side and the heart on the right, a complete viaceral transposition. No pregnancy custed. Death occurred in fifteen days from perioditis.

Wade (4) describes some very unusual necrops, indings. The subject, a colored infant 6 months old died of pneumonia. The appendix, 2 5 cm. long, was found to be congenitally implant in the inquand canal. There was no evidence of appendicatis, nor of hernia. It was evident that the testlick, in its descent had carried the appen dix with it. The tip of the latter was close above the testicie. The excum was normally located.

PHYMOLOGY

A menger knowledge of appendiceal physiology, has been augmented by Helle (s) who states that his studies of the function of the appendix show that the musculature of the appendix lar region and of the appendix Itself act together to insure effectual peristalisis. The walls of the appendix secrete tryptic and amylolytic ferments. There is also an internal secretion of hormones which stimulates periatalists when fojected into rabbita.

The investigations of Walker and Cole (6) which included the fluoroscopic examination of 27 children convince them that the appendix is a specialized part of the occurum with a definite pensatitic and sphincterl action that facult material normally retained in the appendix from one period of digestion to another, provides bacteria for colonic digestion in brief that the appendix is a physiological culture tuber incidentally the frequent occurrence of appendix lar involvement revealed by examination of healthy children was surprising. Waller and Cole believe that appendicitis is essentially a lesson of early life.

Gunn and Whitelocke (7) learned from experiments that the removed appendix ceases contracting when placed in ordinary Locke solution, but when placed in ovygenated Locke's solution at body temperature the contractions recur In appendices removed at operation

there are typically present larger contractions with (usually) superimposed smaller contractions. A removed rabbit a appendix showed similar contractions, very much like these of the appendix in the They conclude that the contractions of the removed human appendix agrostimate those of the human appendix is sufficient to the contraction of the appendix is splanching and pelvic viscersi. Appendices removed from children under ten vears of age possessed the greatest contractions. A severely inflamed appendix may still show spontaneous movements of not definitely abertuant type.

ETIOLOGY OF APPLINDICITIS

The most notew rthy contribution to the etiological investigation of appendicitis is the conclusion of Rosenow (8) that this disease in the absence of foreign body is usually caused by streptococci that these bacteria are located in some distant focus of infecti n that they simul taneously acquire an electi e affinity for the appendix and entrance into the blood stream and are then carned to the appendix. The location and removal of foci of infection is an important measure of appendicitis prophylaxis. The coexistence of appendictti and throat affections is thus expla ned. The danger in appendicitis lies in the fact that the anatomy of the appendix favors strangulation and the growth of facultative and strict anaerobes. In a more recent paper (o) on the elective localization of streptococci. Rose now states that 4 trains from appendicitis produced legions in the appendix in 68 per cent of the 68 rabbit injected which is a marked contrast to an average of 5 per cent of lesions in the appendix in the animals injected with strains isolated from sources other than appendicitis. The localizations of the strains from appendicitis, ulcer of the stomach and cholecystitis as isolated after animal passage resemble one another very closely in cultural and other respects. Those from appendicitis are the least virulent. those from ulcer occupy a middle position and those from cholecystitis are the most virulent. The virulence seems to be one of the factors that determines their place of survival after intravenous injection.

Anderson (10) notes the relationship between appendents and tonstillits. He states that the tonsil is well recognized as a port of entry of many systemic infections, and reports three cases of acute tonsilitits, with apparent subsidence of throat trouble soon followed by indefinite abdominal symptoms. In each instance a gangrenous appendix was found at operation, the summarizes as follows (1) It is important to bear in mind the liability of appendicitis follow

FOWLER THE VERMIFORM APPENDIX

ing acute tonsillitis (2) The appendicular in volvement may be only part of a generalized infection hence the gravity of such cases is out of proportion to the local symptom (1) Such cases tend to become atypical in their clinical course and after smouldering suddenly develop fulminating symptoms (a) Chronic tonsillar in fections, hould be kept in view as the possible cause of similar infections of the appendix (a) At least some degree of local ten lerness and rigidity is almost alway to be elicited on careful examination of the abdomen in the right iliac region in appendiciti though in rare ase these signs may be absent

The investigation, of Savini 11 have on vinced him that minute traumatic less nost the appendix mucosa are very trequent. They are due to the presence of particles of carbon and iron. It these mi rosconi ulcer become in tected necrotic appendiction result. It they remain aceptic the indition found at operation depends upon the tare it connective it ue repair. All tages of repair may be represented in different portions of the same appendix. He consider (fliteration of the lumen to be in variable pathological

Hughes (12 believes that the initial au e t appendicitis is mechanical a rutation it the appendix about it mesenters and the degree of rotation determining the events of the attack This movement is made possible in ı a movable loaded cæcum 2 als 1 tone in the abdominal mu-cles. He affirm, that a proper amount of evercise would decrease appendiciti-

Battle 1 reports two cases in which the mue us membrane et removed appendices was deeply pigmented a Frount h black. The discoloration was contined to the mucous membrane and evidently extended into the cæcum. He had previoully reported tour similar cases nationis were all women, all cawh, in had suffered from bronk con tipation and had had attacks of appendictus. The deposit proved on analysito be iron. Only one patient had taken iron Battle believe that the rollers which grand the wheat for if ur are the wurce. He found unusual traces of iron in flour, but it could not be separated from the ilour by a magnet. He concludes that it is particles may be an etiological factor in appendicitis. The sharp bit, ause traumatic ulcerate n of the mucous membrane

Suzuli 11 made micro-copical examination of 108 appendi es rem ved at operation. He concludes that I The oxyutes may be found in the lumen mucosa or ubmu osa of the appendix without it fucing emptem or anat

omi al hanges. The presence of ox uses in appendiciti i usually accidental inflammation is provoked then many para ites penetrate the wall I the appendix and the abraded to sue becomes intected in m the lumen It is attemely rare 4 The source in cause a non-inflammatory paintul morbid indition in the appendix a companied by trauman lestruction i the ti ue and ham rrhage a pseudo-ar pen li ati a me cerect i che appendix wall are art tact but wa onally a clett 1 1 rmed by the para ite

herrick to report three a e- 1 traumati appendicti Case 1 A young man playin received a hard bl v in the right lide of the abfirmen to the plan handle severe pain i l sed. He ran a tytu al. ur⊶r i apocenticiti and hed nothernth lay haven resid pera tin The autopas hed perit niti and a pert rated at pendix ith a cin rett in in the pert ration. There was robust to tor visu attack but neer no revealed eval ne i nr vi u path logy Cale A traveling aleman by the derailment is a car wa thro magain t the back tithe eatings pto thim. The evere initial pain soon disappeared by retarned a te h ur later with typical ympt m ot appendi citi. Operation revealed a perturated gangre nou appendix. There was hit ry at two preceding attacks (a.e. Alt aced in year wa truk in the abdomen by his brither elbow. He immediately complained of a ere abd minal pain which continued with vimiting and the ordinary vmptom A physician was called on the third day. Immediate operation revealed peritonitis a perforated appendix with gangrenous mucous membrane and a calculus Sherrick quotes the conclum no of Deaver as 1 From personal experience and a study at the literature trauma is ne er the direct exciting cause in a normal appendix appendicitis can follow a evere blow upon the abdomen or severe muscular strain but the appendix will present evidence of pre-evi ting pathology Acute traumati appendicitis is most frequent in males due to their more active hie occurring between the age of 10 and 14. In an appendix previou ly diea ed the hability to an acute a tack toll ing injurdepends upon the legree at mours and the path logs in the appendix at the time of injury

The mortality is high due to late diagnosis rapid gan-rene and pert ration and late opera tion 6 When the hi tory uggests traumatic origin a record hould be made of the cause of the

injury and also of the operative findings

PATHOLOGY

Stickney (17) reports the case of a woman, aged 39 who had had symptoms of chronic appendicatis for a year. At operation a small clubbed appendix was removed. The dubbed tip was a crounscribed solld tumor without lumen examination revealed 5 small myomata in this area. Out of 647 reported cases of tumor of the

appendix, only 3 were myomata. Primary carcinoma of the appendix, although formerly considered an extremely rare pathology is stated by Meyer (18) to occur in o.s per cent of removed appendices. Meyer reports three cases. The diagnosis was made microscopically Pre-operative diagnosis is impossible, and diag nosis at operation unusual. The condition is histologically malignant, but chincally benign nevertheless clinically malignant cases do occur The tumor occupies the appendix tip with obliter ation of the lumen. The growth was noted to be of a yellowish brown color in one case. Rassleur (10) reports two cases. In the first the vellow color was noted on section and the duag none made microscopically. The same color observed on section in the second case, led to macroscopical diagnosis, which was later con-

firmed by the microscope. Pseudomucinous cyst is a truly rare lexion Phemister (20) states that it results from the slow accumulation of an altered secretion of the appendix produced by a mild inflammators process. Most of the cases have occurred between the ages of 35 and so The fluid which accumulates during an acute attack of appendicitis varies from serous to purulent or icherous. The accumulation either disappears rapidly with the subsidence of the acute inflammation or escapes into the pentoneal cavity through a perforation. Persistence of this fluid with chronic cyst formation is rare. However cases are reported of stenosis of the proximal portion, with pus accumulation in the part beyond leading to the formation of chronic empyema of the appendix. Chronic hydrops following milder attacks in which the appendix is filled with a simple serous exudate is also very rare, because the mucous membrane is preserved in such cases, and its secretion changes the character of the contents so that pseudomucinous cysts usually result. The cause of the stenous and retention of secretion is uncertain. It is probable that inflammation and involution are associated in varying degrees in the causation. Often there is no history of preceding attacks of appendicitis. and if so they have been mild. The lumen of the

appendix is filled with a transparent, gelatinous material which is usually quite thick. It contains no facces and usually no bacteria. There are few climical symptoms and development is slow and paniesa. Sometimes the first symptom is the appearance of a mass in the right lower quadrant of the abdomen. Phemister reports a case in which the removed appendix was 21 cm. in length and 21 cm. in its greatest circumference. It was filled with a thick, gelatinous material. Portions of the well were thickened and some of these areas surgested calified plaques.

Phemister states that pseudomyxoma peritonei results from rupture of the cyst. Frankel in roor described the first case arising from a perforated colloid cyst of the appendix. About 20 cases have been reported since. Perforation is usually symptomiess and the pseudomucinous material is disseminated on the peritoneal surface in amous sized masses. There are usually no symptoms subsequent to rupture as the contents are sterile. This condition is cured by removal of the cystic appendig as the source of the mate rial is removed and the remaining portion is absorbed In a case reported by Ogilvie (21) the patient complained of something solid "tapping him on the inside at the appendiceal region while he followed his daily work. A hard irregular mass was polpable over McBurney's point. A roentrepogram revealed a shadow which might be a calcified cyst of the appendix or a ureteral calculus. At operation a calcified appendix was removed. Examination revealed a pseudomyxomatous cyst whose walls were almost entirely calcified. The base of the appendix contained mucord material while the

distal portion was filled with pas. Pfeiffer (22) in a paper on appendicular obliteration states that chronic appendicitis pathologically includes low grade inflammation and end-results of such an inflammation. The latter is evidenced by creatrices, strictures, kinks, and by destruction and replacement of mucosa by fibrous timue, with obliteration of the lumen. The latter is not a physiological process. In 100 surgically removed appendices the occurrence of obliteration was most frequent during the age of active inflammation (so to 30 years) and was not dependent upon the advanced age of the patient. This contention is borne out by a case recently operated upon by the writer The pa tient was 70 years of age and the appendiceal mucosa was gangrenous with obliteration of the lumen only at the tip. Picifier classifies three types of symptoms due to an obliterated appendix (1) reflex, due to irritation of the pervous mechanism of the appendix (1) local due to mesentieric and peritoneal contractions and in flammatory bands and adhesions affecting the appendix or contiguous bowel () consecutive symptoms general and local consequent upon disturbed function of the illeocæcal region buttin local and consecutive symptom in the insulant contractions are the operation permanently relieves the symptom producing contractions sclerosis or adhesions. The determination is these latter conditions and the appropriate treatment there to remain surther observations and experience.

Another type of obliteration is described by Bonn (2) who reports seven cases of phiform appendi es. A filitorm appendix so named and described by Fastman (24) is a lend r whit cord usually covered entirely or in part by a pericologic membrane. If only partially exered the unconstricted portion may be of normal 120 The end may be free or attached to the parietal The constricted part is with ut pentopeum A filiform appendix may be mi taken t r an adhesion or the appendix may be considered congenitally absent or pathologically destroyed Bonn believes that two processes are associated in the production of the filiform appendix name. ly a chronic inflammation and an involute in fue to constriction by the accompanying periculonic membrane

Judd (25 reports a case of auto-amputation of the appendix a term used by Murphy (6) ludd's ase was a young man with indefinite symptoms of appendicitis. During a kidney operation the appendix was brought into the incision. It was connected with the accum only by a time adhesion. Pinching at this point with the fingers entirely separated the appendix from the cacum There was no opening into the The proximal end was also closed cæcum appendix was 7 cm long not dilated and con tained a small amount of muroid material showed the lesions of a chr nic interstitual in flammation

DIAGNOSIS

The diagnostic value at rigidity of the right rectus has been so greatly emphasized according to Randall () that many cases of appendicitis have been neglected in the absence of this sign. He states that ordinarily rigidity of the right rectus is a reliable guide, but in some cases rigidity of the right external oblique is present in its stead. These cases are mild many patients are about and attending, to business, and a high polynuclear count is the oil indication of a

serical condition. In every of cases seen the partivear by Ran fall, with right to of the right external ellique and not of the right rectulate arpen lie was retrocased in retrocase.

Ten Horn (8) report that tract in upon the interfer spenial is of produces pain in algorithm to the horizontal in aut of reas. The circles era pelad see the testi an Lenth pulled without making produce in the test. He behaves the pain to be due to irritation to the peritoneum thout the internal ring. He fould this value of the create area relations.

Ruthkeyitch (a) believes that highic armen de iti i frequently diagn red a some fun ti nal ga tric or inte tinal discreter i ners u rienn Many patient given hit ry et previou atti k r it haracteri tic pain. Cin tipation ten ler nes at M Burney peint and temperature are iter negative Ruthlevitch cull n t eheit Keysing sign and leuc action was present als once. He concludes that there are redright stic ign of chronic appendicity. Palpation i the best kurle. He palpated the appendix in to per ent of cases and main vas produced in 48 per The palpation also caused pain in the upper abdomen at the same time in many uses Hi method of palpation i as fellow. The fle ed tingers of the right hand are pressed down between the external wall of the cacum and the abdominal The tingers are then extended and an endeavor made to deflect the cocum toward the median line. This manipulation invariably produces pain in chronic appendicitis

Bichoff (so distends the previously emptied bowel with air through a rectal tube. By this means pain over McBurney's point is elected if the appendix a softmarily observed should not be considered diagnostic of uppendicties as it is aused by other conditions.

Lanz (31) states that frequent and painful urnation in children may be an early single of appendictus. When the targer is introduced into the right ingunal canal the muscles contract about it if the appendix is inflamed. The cord is painful and tender. Contrary to Ten Horn Lanz believes that the "remasteric reflex is weak or about in acute appendictis."

Sutton (3) reports a case of appendicitis with unusual features in a young unmarried woman. At 5 am he found the patient suffering from intermittent olicks abdominal pain abdomen tympaintic temperature and pulse normal. No aldominal tenderness. He gave soap-suds enema liquid diet and castor oil. Diagnosi acute intestinal indigestion. At 4 pm in the tempera.

appendicitis by palpation and \ ray This was confirmed by operation and the patient has re gained her normal health Kenefick says. The irritation or traction spasm originates at some particular attachment of the appendix to a branch of the mesenteric plevus and reaches the musculature of the stomach by way of the mesen tenc and celiac plexus as follows (1) hepatr plexus and plexus gastroduodenalis to the pylorus (2) plexus gastro-epploica dextra to the pylorus and lesser curvature (3) plevus gastroduodenalis to the fundus and region of greater curvature Afferent impulses in general pass from an inflamed appendix to the mesenteric gangila uprarenal ganglia, vagus to medulia and c rte independent of the spanal centers

Aaron (40) previously had noted that pressure over the appendix caused epigastric pain. R cantly while examining a case of chrone append citis with the fluoroscope be induced a pylorospasm by pressure over the appendix and coincident epigastric distress of which the petitent had frequently complained. Aaron be beves this reflex pain is caused 1 v pylorospasm and ventures the option that the gastric symptoms of appendicitis are also due to the spassm.

Aynesworth (41) states that the average incidence of appendicitis in children up to 15 years of age is 15 per cent. The large number of pus cases are due to late diagnosis and rapid d velopment Cases have been reported as early as the fifth week. Fallure to make a diagnosis to oversight rather than to symptomatology Unfortunately other acute wild abdominal conditions are common leading to late diagnosis, and children do not readily localize painful areas. The history is scanty Nevertheless Aynesworth believes that the diagnosis can be made fairly early. Abdominal pain is usually the first symptom. Children with even slight pen toneal avolvement protect the abdomen very carefully The appendix may be anywhere in the abdomen. When it lies in the pelvis there may be no abdominal rigidity and tendemess only deep in the pelvis. In the presence of bladder irritation or doubt of diagnosis a rectal examination should be made. I ain, vomiting tenderness, rigidity in any part of the abdomen and fever strongly indicate appendicitis. Gastroenteric affections must be excluded. Lagming tion of the lungs should be made in children whenever an acute abdominal condition is pre-

Fleischner (42) reports the following case A child 8 years of age became acutely ill with fever vomiting and pain in the right side of t abdomen Twelve hours after the onset the was a leucocyto-ia of 30 000 A tentat: diagnosis of appendicitis was made. Up examination light percussion of the chest vealed relative duliness over the right lower lo f the lung and on auscultation the breathing v slightly diminished. There was no distention the abdomen and abdominal respiration v normal Consideral le pain was complained over McBurney point and extending upwabut neither tenderness nor rigidity was co mensurate with the pain. Operation was no poned f r twel e hours. At this time pneumor symptoms were in re evilent. In twenty for hours there was no loubt of rneumonia a nam had drappeared

(age (43) tates that pain tenderness, a muscular pasm in the right lliac region occ during typhoid and render differentiation fro appendict s difficult. The difficulties are c cased by the fa t that the appendic does sha in the intest nal lesions of typhoid as instance by case reports of ruptured typhoid ulcerati f the appendix. Gage divides the appendict of typhoid into 3 classes (1) appendicitis. aculental accompaniment of typhold or chronic condition become active (2) typho ulceration of the appendic (3) appendicities curring a soon after typf old as to be due pro ably to it. In unusual case of post-typho appendicitis wa reported by Stokes and Arni (44) A young man who had had typhold ears hef re de reloped acute appendicatis. T appendix was gangrenous and the bacillus Eberth was cultured from it The Widal res tion was positive. Was he a carrier. Seven cases have been reported of accidental complic t on of appendicatis without evidences of typho involvement but due to mi ed infection wit ut typhoid bacillus. Gage reports a case which acute right iliac pain rigid rectus as vormting developed when the typhold temper ture had been normal for five days. The le cocyte count rose rapidly to 18,000 Laparoton for probable perforation revealed an unrupture gangrenous appendix lying in a walled off abscer The pathologist reported typhoid ulceration as the presence of typhoid and colon bacilli as we as streptococci Gage believes that caref evamination of removed appendices for so-callaccidental inflammation would reveal the preence of typhold leuons in many cases. I emphasizes the importance of a rising leucoes count.

but soon recovered. Names and voniting were followed by relief. There was sight tenderness in the lower right quadrant. At operation, upon delivery of the appendix, the partially amenite the pattern of the spendix to inflate starmingly. Pressure was required to accomplish defiation. The appendix contained a No 6 bird shot. There were no inflammatory changes. Waller believes that this clue accounts for hitherto puzzling attacks of soute coils in which the appendix was not pathological but contained small concretions or foreign bothes, these concretions or bothes acting as a ball valve preventing ready defiation and productive symptoms of coils.

Strauss (55) reports tive cases of extrapen toneal appendicitis which he classifies under three heads (1) Those presenting a straightforward picture of appendicatis. In these cases the appendix cannot be found until the peritoneum is incised near the crecum and the latter lifted up (2) Those simulating a perinephritic abecess. This type is characterized by pain, tenderness, and swelling in the right lumbar region. Through the lumbar drainage incision it may be possible to remove the appendix without enter ing the peritoneum. (3) If the appendi is not removed a persistent feech fistula may result. Fortid pus obtained from a lumbar abscess is probably due to disease of an extraperitoneal appendix. Careful search should be made before deciding that the appendix is absent or has aloughed away

Lichty (56) who reports about 700 cases of appendicitis from the view point of the internist, is impressed with the fact that many cases of supposedly chronic appendicuts are operated upon without relief of symptoms. He summar izes as follows (1) A close co-operation of physiclan and surgeon is necessary to obtain the best results. (2) Since only 8 patients out of about 700 under all conditions and circumstances, died the disease need not be considered with such (Lichty refers to causes hurrledly diag posed and operated upon for chrome appendicitis in which there may be no pathology in the appendix.) (3) An early operation during the first acute attack is not only safest but will likely prevent a life of more or less chronic invalidism. (4) A careful routine study of the leucocytes in acute appendicitis is of diagnostic value. (5) A routine study of the gastric secretion in chronic appendicatis yields valuable information (hyper chlorhydra) (6) The end-results in cases of chronic appendicits are often unsatisfactory and cannot be definitely foretold.

TREATMENT

Guthne (57) reports the use of the serum and vacene of colon bacillus in its cases of appendicitis. All recovered without operation. There was one recurrence here too little of the serum as used and no vaccine. The relief from pain was striking. Serum should be used before pain was striking. Serum should be used before pain was striking. Serum should be used before pain becomes localized. He gives so can, of the serum and a few days later 100,000,000 colon bacillus vaccine to prevent recurrence. The firstion of complement test should be made and if some other organism is the determining cause a corresponding serum or vaccine is indicated.

Syms (58) reports a mortality of 100 per cent in a series of peritonitis cases of appendiceal origin in 1904. The mortality of a series in 1012 was 16 per cent, Improved operative methods have decreased the death-rate. Syms agrees with Murphy that perf rative peritorities tends to be localized or general from the very start, depending upon the kind of bacterium responsible and the patient's resistive power He disagrees with Stanton (50) in his conclusion that dissemination of peritoneal infection is largely a matter of penatalsis and that the quiet afforded by withholding food and water by mouth will prevent its spread. Syms believes in imme diate operation at any stage of appendicutes. If infection is present a rapid, simple operation with drainage is indicated the drains being placed between the intestines and the panetal neritoneum. The after treatment consists in washing the stomach if there is nausea, vomiting or extreme sepers and withholding food and water per mouth for 4 to 48 hours, keeping the patient in the Fowler position use of the Murphy drip clear by the lower bowel by enemata to relieve distention no cathartics, few drugs, no opsum stimulation if necessary. If the pulse or heart is weak the Fowler position should not be used. Post-operative ileus is due to spreading pentonitis septic infection, excessive manipula tion at the time of operation faulty placing of drains failure to empty the lower boxel before distention, and the use of morphine or onlum.

The principles of the Ochsier method as out here by Histo (so) are as follows. The medical treatment, if it can be called such, consists in the problibition of food physic and generally of water lavage at times rest in bed mild beat applied locally. All cases seen in the first 14 hours are operated upon at once if willing a few are operated upon on the third day but cases from the fourth to ninth days, expecially if

very ill are treated medically until a safer time for operation

Deaver and Pfeiffer (61) agree with Ochsner in their statement that early operation in appendicular peritorities is the rule, but is of no benefit and may be harmful in cases of more than 40 hours duration with signs of diffuse peritoritis and marked systemic tovernia Removal of the appendix is of no avail as that organ is buried in a mass of omentum and coals of intestines and is incapable of adding to the infection. Spreading pentonitis cannot be checked by surgical means The best treatment is supplying rest to the alimentary tract by withholding everything by The Fowler position and enteroclysis are important. When the outlying inflammation subsides and localizes about the appendix the latter may be removed or the pus which is about The after treatment consists in the sitting posture enteroclysis nothing by mouth and careful nursing

AN ESTRETIC

In a consideration of choice of an anaesthetic Bevan (62) states that drop ether should be chosen today as the standard general anaesthetic when a prolonged anaesthesia is desired with relaxation and unconsciousness. Gas should be chosen in short anaesthesias and in special cases such as kidney mufficiency. Local infiltration anaesthesia may be used when the surgeon has the full o-operation of the patient and when the field of operation can be completely inhitrated and an esthetized by a safe amount of novocaine and cpanephrin. He belie es that nerve blocking should as a rule be consined to nerves which are exposed by a dissection done under local inhitration as in a hemiotomy.

Harris (63) reports 34 appendectomies done under nerve blocking. The appendix is insensitive but novocaine must be injected at the base of the meso-appendix. The method is safe and free from the dangerous sequella of general anasthesia. The psychic element has been over estimated Dread of operation is based upon fear of pain which may be abolished by assurance that there will be none upon loss of consciousness v hich does not obtain with local ancesthesia and upon fear of the outcome. This fear may be mitigated somewhat by the fact that patients are apt to consider an operation which can be done with local anæsthesia as less severe than one requiring a general anæsthetic. Nerve blocking teaches the surgeon to employ gentle manipula tions which tends to decrease shock

Braun (64) says The writer confesses that

after many attempts some of them dating back a long time he always returns to the same conclusion that is to perform operations on the appendix under general annesthesia without local anesthesia.

1501 105

Our views in regard to the most desimble in cision for appendix removal have recently been modified. Brickner (65) states that the Mc Burney incision is satisfactory for a simple appendention but a presumably simple appendention requiring liberal exposure. The incision is not suitable for exploration of the upper abdomen so often indicated nor does it lend itself to enlargement. Its routine use would lend to otherwise avoidable technical difficulties and conditions might be overlooked which would be observable through the right rectus incision.

Harrgan (00) describes a modified McBurney incision for the treatment of appendicutes and pelvic disease as follows: 1) After removal of the appendix the peritoricum and internal oblique and transversalis muscles are situred (). The skin incision is extended downward and inward toward the median line (3). The aponeur ross of the external oblique is divided to the point where it fuses strongly with the anterior rectus sheath. (4) The anterior rectus sheath is incised parallel to the line of tu-ion of the external oblique muscle leaving a sufficient mirror uniterally to suture (5). The rest in muscle is freed displaced and retricted cutward.

(6) The perstoneum is incised Rockey (67) describes the trans crsc incision as follows. The skin incision 2 to 2 inches long is made directly transverse with its center at or near McBurney's point. The outer part of the rectus sheath is incised dividing the tendinous border and the aponeurosis of the muscles on a directly transverse line. The scalpel handle is inserted below and the finger above and the wound pulled wide apart without cutting any muscle fibers. The external oblique fibers are retracted at the outer angle and the rectus at the inner angle. The peritoneum is divided trans-Definite pre-operative diagnosis is essential as this incision is not adapted to other pathological conditions. In interval cases and acute cases before rupture the operation is facilitated and firm union obtained. In pus cases it gives direct approach Drainage is placed in the outer angle of the incision and the outer side of the cacum Rockey believes that liability to hernia is diminished

OPERATIVE TECHNIQUE

Torek (68) has described a combined incision for appendectomy and right hernhotomy. The skin incision usually employed in hernhotomy is prolonged outward and the appendix is removed through a muscle splitting incision beyond the internal ring.

An interesting variation of operative technique is described by DeTarnowisy (69). He advocates the routine removal of the appendix through the internal inguinal ring during right hemiotomy. His results have been satisfactory in over 50 cases. The execut is distant only 4 to 6 cm from the internal ring and can be partially or totally delivered. If the ring admits two fingers or can be easily stretched to admit them he delivers the curcum with the index and middle ingers. A freely movable appendix may be delivered with the index finger alone. Gross pathology was evident in 50 per cent of the appendixes thus removed. He does not advise this route in acute appendictis.

Neill (70) describes Cullen method of exposing a retroescal and densely adherent appendix. The base of the appendix can usually be located. When this is accomplished blunt forceps are pushed through the meso-appendix at this point and a tape drawn through. Traction upon the ends of the tape brings up from three fourths to one inch more of the appendix. Another tape is inserted as before and this maneuver repeated until the appendix tip is delivered. Usually three tapes are sufficient. The meso-appendix is clamped off and the remainder of the operation

carried out according to indications. White (71) reports a case of appendicitis, drained with a rubber tube in which an active hemorrhage began four days after operation and continued twenty four hours although packing was tightly inserted about the tube. He believes that the hemorrhage was produced by eromon of the deep epigastric artery by the drainage tube Fatal hemorrhage has occurred from this source The artery is frequently exposed with its companlon veins, in the incision. White applies two ligatures about one inch apart to these vessels in the lower angle of the incision anastomosis insures adequate blood supply believes that ligation should be routine in this class of cases.

Pettit (72) describes a method of drainage through the McBurney incision. The drainage tubes lie close to the filum at the outer end of the split in the internal oblique and transversalis. These muscles are then autured to the tubes. A shi is made in the c ternal oblique close to the lilium and the tubes are drawn through. Flazilithey are brought out through a corresponding small skin increan close to the anterior superior apine. The drainage canal is thus placed be tween the execum and the bony wall of the pelvia. Primary union of the operative incision is facilitated.

Benjamin (73) deprecates the practice of leaving the raw appendix stump uncovered as adhesions are in ited. Nature must cover it over with tissue, resudate

Carter (74) describes his method of disposing of the appendix stump a fillow. The appendix stump a fillow. The appendix is champed near the base and cut if. The audure is threaded on a round needle. The needle is inserted into the "ecum about one fourth inch from the stump and emerges about one-fourth inch bevond parallel with the base of the appendix. Repeating the maneu er twice more sur rounds the stump with a triangular stitch. An assistant erts the tump int the bowel and the suture is tied.

The Mayo (75) append it ms so beautifully demonstrated by the tereording of Kelly is probably the best known method. The writer expresses continued to indence in a procedure which he has previously described.

CCUPLICATI N

As a complication f appendicuts, Delatour (77) reports seven cases | pel ic abacess follow ing the Fowler position. The patient does well for a time although there 1 persistent alght elevation of temperature. The incisi in has ceased to drain and the patient may be allowed to go home with a temperature slightly abo e normal Others suddenly recover Delatour belie es that all these cases have undetected pel ac abacesses of comparati ely slight virulence Sudden recovery is due to rupture of the abscess into the rectum. In this series the abovess was disclosed by rectal examination Trentment consisted in incision per rectum unless the abscess was located high up in which event it was aspirated

Babler (78) believes that pylephlebitis with multiple absences of the lung or la ru a more frequent compilication of appendicitis than is realized. In a typical case the diagnosis resis on () the history showing that the uppendix was the primary sext of trouble (2) the shifting of the symptoms from the append to the hepatic region (3) the progressive increase in the severity and character of the symptoms (4) the repeated chills followed by high pulse rate and marked elevation of both temperature () the jumidice (6) the perustent pain in the hepatic region (,) the urnary and 11 sol lindings (8) the change of liver duline () the picture of marked toximia and (10) the absence of the signs and manifestations of extense peritorities Multiple absence of the lings is in licated by repeated chill septic temperature and persistent cough. The only high period of the lings and draining the absences is Ballice reports three cases to write absences in the liver one of the lings. All were discusses in the liver one of the lings.

Mark is tool quotes Deaver to a follows The earlier the operation if r appen liciti dur ing pregnancy; the less the likelih at of infection of the night tulk and o ar and the less likel therefore the development of sen u complications. I have never had digital n acur in preg nant women up n whom I have perated for acute appendiciti unles the right utenne appen lages are in old in the disease and wilder then Mark a believe that abort in in these cases i caused by undue han lling of the nterns and alness He reports the cases Case 1 Age 23 I para hal hal acute pain in the appendiceal r gion for some time. Examina tion revealed a five minth pregnancy there wa acute pain a little als ve McBurney point and some rigidity of the right rectus. Incision wa male at McBurney point. The appendix was t unlt be adherent t the ascending colon The greatest care was taken that the uterus fall plan tube, and overs were not injured or manipulated they being held to one side with a nal wet with normal salt solution. The appendix wa rem el The patient made an uneventful re overs and four months later was delivered at full term Case The patient was suffering severel 1th marked rigidity temperature 101 F a white cell count of 10 000 and poly nu lears b. Immediate operation was advised and the advice ac epted. A median incision was made from the umbilious to the symphy is. The omentum extended down over the right tube and ovary being firmly adherent to the uterus omentum was tied off then the appendix which was embedded in this mass was field off and the stump buried. This left a mass consisting it a piece of omentum right tube overs and appen dix attached t the uterus and right broad ligament. The right tube was very gently ned off and cut away and the adhesions which held the appendix omentum and ovary were then removed from the uteru Stal wound drainage was privided. The patient aborted with a 4.5

month fatus within twelve hours of operation Otherwise her rec very was unevatful. Markoe stat that the appendix is not dra'vn up into the abdominal cavity by pregnancy but on the contrary may be brought up with difficulty into the into 1 n

Wallace (81) reports a case of ruptured appen dix at full term pregnancy as follows. The patient called him at night for upposed labor pains. He f und her sitting up and complaining t severe pain low down on the night side. There as shight cerrical dilatation. The head was not engaged. The next atternoon she was still in pain and had been continuously. Tempera ture 103.6 F rulse 1.8 Vamnal evaminati n revealed no increase it dilutation but sign of abuce in the appendix region. An ice car was applied in the hope that perati n could be delaved until after delivery. The next lay the temperatur was roa F pulse rao Armen dectoms was performed and the aboves drained The incisi n was closed with exceptional care about the drains in order to with tan I the severe train of labor. Closure wa difficult and he believes would have been impossible had he not incised the fascia tran creek. The ne t lay after one and one halt hours of labor a normal delivery was accomplished under anasthesia Recovery was un ventful. The dillication of McBurney ox int in the pregnant abd men was naticeable. It a difficult to determine a here to make the incision

191111

Bunts (82) reports an interesting security of appendent my. The patient was a nurse wh had had a clean appendectomy performed several vears previously. She was free from discomfort for nearly a year after operation when he again complained of pain in the right sid attacks were very severe. Examinate n rev aled a somewhat enlarged mary. At operation the right overs was found slightly enlarged and evitic. At the site of the termer purse string suture on the recum was a white ring which formed the base of a conical prejection of the bowel about one inch in length. Fearing the possibility of rupture of the thin-walled liver ticulum and that distention 1 it might cause olic Bunts invaginated the protrusion int. the cæcum and secured it with a double purse tring suture. There has been no recurrence of pain He has since found the same andition in two other cases but in lesser degree. In all three cases the right o are no al normal and might have a counted for the pair of which they all

complained. He believes the condition to be not uncommon and that future observation will prove it to be responsible for recurring pain in

the right side after appendectomy

Case (8x) states that a common cause of creed stans is adhesions, usually associated with disease of the appendix. Immediately following recovery from appendectomy there is usually considerable carcal stasis. Following the attempt to expel the barrum enema, it is seen that the caecum has failed to contract, the peristaltic waves which evacuate the large bowel commencing at or above the fleocecal junction instead of at the tip of the Fven several years after operation carcal stasis persists in many cases, a round residue of barium the size of a ac-cent piece remaining in the crecum after the colon is otherwise emptied of barrum. This is especially likely to occur where the patient complains of a tenderness of the caccum. Sometimes this carcal stasis was present before the operation, but often exists after operation where it did not exist before. He believes that the rounded barium occurs at the site of the stump of the appendix and that it has some relation to the invarinating suture by which the stump is buried This suggests the desirability of including the least possible amount of crecal muscularis in the suture.

In a series of 276 cases of intestinal obstruction reviewed by McGlannan (84) or were post operative. Nearly 40 per cent of the post operative obstructions and 10 per cent of all cases in this series followed drainage operations for appendicitis. This is a potent argument in favor of early operation at a time when no drainage is required. Had these nationts been operated upon early all would have been spared a second operation as a result of which o died Prompt operation in appendictus and careful covering of surfaces in all abdominal operations will afford efficient prophylaxis against post operative obstruction.

In a series of cases of acute intestinal obstruc tion reported by Deaver and Ross (85) 81 were due to post-operative adhesions. Fifty-one cases followed operations for appendicitis and 44 were drained at the original operation 27 died.

PROGNOSIS

The prognostic value of post-operative leucocyte count is discussed by White (86) states that a secondary peritoneal infection with good resistance shows an early and marked increase of leucocytes and will continue for some time. The leucocyte count is a safe guide as to conditions within the abdomen. In general

peritonitis a constant low or declining leucocytosis denotes a grave prognosis.

Eisner (87) believes that an unusual amount of urobilinogen in the urine during appendicitis indicates a destructive lesson of the appendix.

Turner (88) states that the mortality of appendicitis should be less than a per cent. Early operation would decrease the death-rate to I or per cent, or it might become practically nil. Appendicitis is not inherently dangerous. The result is a question of degree of peritoritis and the stage of the disease when operated upon. At present over 60 per cent of cases are operated moon when involvement is localized. Ten years ago conditions were reversed

Kakels (80) belie es that the majority of deaths from appendicitis are due to failure in making a diagnosis, the abdominal pain being assigned to other abdominal organs rather than the appendix. Early diagnous should be easy if we remember the following train of symptoms andden generalized abdominal pain, gradually becoming localized nauses and vomiting general abdommal sensitiveness, local ngidity elevation of temperature leucocytoms and rapid pulse

Murphy (00) makes the startling statement that the mortality of appendicitis in the hospitals of the United States is 10 per cent. This death rate is due to procrastination. The early symptoms are usually diagnostic later they are obscure. Early symptoms are no guide to the probable outcome I am and temperature may be gone by the second day which may mean resolution or gangrene A gangrenous appendix produces neither pain nor leucocytosis. The next symptoms are those of general peritonitis. The mortality in childhood is three or four times as high

CONCLUSI N

The incidence of primary carcinoma of the appendix suggests the advisability of routine appendectomy during laparotomy

z Infection of the appendix by bacteria car led through the blood stream from a distant focus is an established fact.

3 Typhoid fever and pneumonia in their early stages, may be difficult to differentiate from acute appendicitis.

4. The chief symptoms of chronic appendicitis

may be referred to the epigastrium.

Undue retention of barium in the appendix and tenderness of that organ elicited under visualized palpation are roentgen signs of great diagnostic value.

6 Appendicular bliteration an end re ult of inflammatory hanges and it is selected ductive of symptom

Excepting the trank case of a ute appendientis diagnesti uncertainty or coincid no pathology emand ample in then hence the nght rectu aper sich

8 The mortality of appendictrial too high Early diagnous and early peration are e untial

to low mortality

ABSTRACTS OF CURRENT LITERATURE

GENERAL SURGERY

SURGICAL TECHNIQUE

OPERATIVE SURGERY AND TECHNIQUE

Primrose A. The Physics of a Surgical Dressing with Special Reference to the Harmful Effect of Using Impermeabl. Material Over Septic Wounds. B i M J. g. 218

The author r fers t n article by Sir Al proth Wright in which Winght also it with use fise hum chlorid si rent with sodium cit it o sper nt as a soluti n for moist Ires ings the being cov ring 1h author ered by an imperviou objects to the use of an imperviou A TIME OF E moist dressing that drinage is lear I He cut's existing his to ship that far illary attra tion is I seened or made nil when exportation in m part of the lessing a prevent d. The aperiment were carried out by using il sks ontaining vater a gang with being saturated and placed therein with one end pretruling A cry tal of an aniline live nas then fit ed in the will It the flask nas uncover 1 th ly rose in the wick whereas if an impermeable substinc was placed ov r the flask the dy lel not rise This objection to Wright a recommendation says the author is especially tenuble h re the wound is an infected one where drainage is greatly to be desired. I H SEILES

Fisher II E Non-adhering Surgical Gauze J (m U (1910 l 1930

Fisher has experimented with various materials in the dressing of open wounds. Absorbent ofton chamola skin and powders he rejects as unsatisfactory. Cutta percha and silver foil if perforated give fairly good results. Ilain surgical gause is attisfactory, except that it adheres to granulating wounds a disadvantage which is less troublesome if narrow mesh gause is used. Medicated gause he found to have no particular advantage over plain cause.

He secured the best results from the use of gaure impregnated with parasi in in the following manner Eight parts of parasin mixed with two parts of white petrolatum and larolin is boiled for ten minutes. Then dry sternlized gaure in strips is immersed for ten minutes in the mixture. The gaure is gradually removed and stretched and allowed to dry in a current of filtered air which frees the aper tures of excess parasin. In use one layer or two is placed in direct contact with the wound or raw.

urfa in Forlinary su go all gauze fluth. I is placed along it. This give can be changed as frequently is. I in I that the waved gauze can be left on for a vin derible period. Vethe vound hada it is lifted on.

norifabl penod 2) It awes no pain a disomtore on a plication or removal. (3) The parafin i i not absorbed and the gauzolees in the ome matted with secretions and I bris. (4) It losely confirm to the urface to which it is applie. I (5) It allows adequate drainage of the would be retions through the neshes. (6) It is easily and quickly sterilized by immersion in absolut grain all ohol (7) It is of particular value in the treatment of skin grafts.

ASEPTIC AND ANTISEPTIC SURGERY

Frazer J and Bates, H J The Surgical and Antiseptic Values of Hypochlorous Acid (Eusol) Ed b M J 9 0 7

The method of preparation of eusol is as follows. In a quart bottle 27 gm of dry bleaching powd r are placed 1 liter of water added to this and the mixture shaken. Then 27 gm of boric acid are added and the bottle filled with water after standing for a few hours the mixture is filtered. The filtrate is eusol and contains about 0 5 per cent hypochlorous acid.

Gunshot or stab wounds packed with gauze scaked in cusol solution show beginning granulations within 36 hours. The objections made to the use of this solution are the pain it causes the irritated and soiled condition of the surrounding skin and the arrest of wound secretion. Vecording to the authors, all of these objections are negligible.

The solution has been used with mestimable benefit in gai gaingree and in compound fractures complicated by infection in disintegration of joints in compound fractures of the skull in emprems and after inflammation or wounds of the adominal cavity cusol has been of benefit in pre-enting suppuration and arresting infection. A number of cases of acute toxemia subsequent to wound in fection with a gas producing organism have been treated by intravenous injection of cusol in amounts.

varying from 4 to 70 ccm. to which was added sodium chloride in the proportion of 0.85 per cent With this method of treatment most gratifying results have been obtained. E. K. Austracow.

Clinical Report on the Application of Eneol; Report to Medical Research Committee. Lenct Lond 916, crc, 356.

The Medical Research Committee of the Royal College of Surgery of Edihourgh has presented a very lateresting report on the use of ensel in the treatment of womds. Several cases are cited to flustrate the use of the solution in both asseptic and septic wounds and i flustrate its value in serous and synovial cavilles and in inflammatory lesions of various types. They advocate its usefulness in womds which have become septic after certain operations.

Their general conclusions are that eusel in a great variety of cases has proved to be non tone and non-initiating, as well as an efficient antiherite. The action of cased depends upon the free those chlorous acid which is liberated by the cusel. There is also a sufficient quantity I biborate of calcium to give the solution a slightly sikaline rection. This feebly sikaline so it from can be introd ced into wounds or serious cavities with perfect safety It can even be left in such cavities in quantity without any harmful effect. In lacerated and contused wounds, not in compound fractures, such as are met with in military practice, the committee found it to be the most efficient safespite.

It is most off enclose during the period of what might be termed progressive septals. Some surgeons have emphasized th benefit of modifying the treat ment when septals is substilling or has ceased. The granulations form after a period of two to three days and rapidly cover the surface of the wound. Any tendency to superabundant growth of granula tions and consequent delay in healing can be coun teracted either by so applying the cusof that the serous duchange is reduced to a minimum and the wound kept day or by discontinuing cusof and using other dressings appropriate for healing wounds. In any event the septis is by this stage completely under control.

The freedom which can be exercised in the applies ton of eusol, and the rapid ction which it has in arresting the sepsis and discharge of an infected wound, led to experiments on the effect of cusol on the blood. Following this, eurol was employed in the treatment of general sepsis touchula by intra venous infection.

This method was first made use of by Lorrain smith Ritchle and Rettle 1 case of grave preparal septicemis, and the result was the recovery of the patient. They has a size applied to treatment in other similar conditions. In several cases (coremia has been successfully overcome, and although such a result has not been uniformly attained, the safety of the method juriflies its being milted in the diseases referred to in their preliminary communication I tra enous injection has also been applied with success by Captain Fraser and Captain Bates in cases of cut toxicmia secondary to gas gangrene.

Further research is now being curned out on the development of the subject foreshadowed by these

investigations. The lotton is exceedingly inexpensive. The ingredients are procurable anywhere at a slight cost, and the preparation is very simple process. Eupad powder is emposed if equal wrights of boric ed and blenching powder. The books acid is in sufficient excess: set free the bypochlorous acid it the solution. The blenching powder should be dry and abould co tann #8 to 30 per cent available chloring.

The sol ti cusol is prepared as follows. Add to liter of water 5 grams of the power shake well and Bow it to stand bour then filter. The clear solutio is evend, and co t in bout c 5 green hydrochrours aird. If the bit ching powde is id or not p t the strength given above twe larger quantity of the powder.

ARESTHETICS

Jackson, D. E. Some Observations on Anasthesia and Analgesia. J. Pherm of 1 p. Th. p. 9 6 vm, 3

Tackson calls ttention t the f that for ber of years past nitrous oxide ha bee consta thy growing I fa or as general mestbetic and anal Thus has been mad possible m nly he states, by the introductio f impro ed methods of dministration. The duration of the næsthesia under nitrous oxide has also progress rely increased from an average of only min t or two pt an average of perhaps ten mm tes o konger and J cl. son states that he has been ble by method to keep dogs aniest betized for periods up to five and one half bours. Quit recently he at tes there has been alight tendency to void the use of nitrous order in any prolonged operation (half hour or more) because it has free ently appeared that the after-effects of prolonged nitrous-oxide anaesthesia were more deleterious than those of ether He believes that this is mainly dot the use of improper and unscientific methods of d ministering the nitrous oxide. He maintains that the cost of nitrous oxide by the method which he has made use of may be reduced to about to or 35 cents per hour for the human subject.

George E. Bella

Walter W. An Apparatus for the Administration

of Gas-Oxygen. H Y II J 0 0, cell 352.

A new apparatus is offered which combines simplicity portability efficiency f eedom from pres-

sure addition of humidity a curacy the washing of gases the warming of gases visual evidence of the ratio between the gases and a provision for rebreathing with or without ether sequence and with out the removal of the mask. The gases are passed through warmed water by means of respective tubes and the evidence of the quantity of gas is shown by the levels of the water in these tubes. A table of ratios is placed in view between the gas-tubes and for any given volume of nitrous oxide as evidenced by the level the desired percentage of oxygen for that particular level may be read and instantly provided by readjustment of the oxygen valve apparatus is illustrated and the technique of its application fully described in the original article E. K. ARMSTRUNG

Aikins, W. H. B.: The Advantages and Risks of Combined Local and General Amenthesia (a. d. P. a. t. e. R. t. a. t. a.) of

The author limits his discussion of the use of combined local and general anasthetics to operations about the nose and throat. Hewitt stabulation of advantages claimed for such a combination

I The elimination of the element of far to which a certain number of an estheti de th. are

The production of a sommolent or apatheti on litton which fa thit ites anaesthesia

3 The absence of excitement during anæsthetiza

4 A diminution of the amount of the general anaesthetic necessary to produce the necessary relaxation and depth of anaesthesia

5 The diminution of secretion especially that of murus under ether

6 Lessening I the tendency to vomiting and pulmonary complications.

7 Lessening of the tenden v to shock

8 A longer period of insensibility after the end

of the operation redu ing the discomfort and pain.

Adrenalin and cocaine the only local anisothetics considered in this article must be used with great care and discrimination. They should be applied at least one hour before the induction of general anisothesia.

Many authors are quoted who have observed sudden death follow the injection of occaine adrenalin solutions during a chloroform anneathesia. Dr. Goodman Levy has been able to produce ventricular fibrillation in cats almost at will by in ections of adrenalin during chloroform anneathesia a phenomenon which has not followed ether anxes thesia. Whether or not the disturbances noted are due to rapid absorption of adrenalin from the submucous tissues or to direct infection into a vein has yet to be determined. But the undoubted risk of using cocaine and adrenalin in combination with general anarethesia indue of ith r ompietely or in part by chlorotorm has been d infiely proved. The author concludes with an emphatic protest.

again t such a combination of local with general anaesthesia E. Fi curr

Hanes G: Spinal Ansesthesia Lon / 1/ A J 10 6 \ 1 289

The author bases his discussion upon so re tal cases which he has observed. He claims that the advisages of spinal amenthesis over all other methods are than it assess the most perfect relaxation of the parts which it is possible to obtain any that the patient bas less post-operative discomfort. In the discussion of the technique the usual points are emphasized the proper type of needle (short sharp point) and all glass syringe the proper print for injection, the upright position of the patient and the proper strength of solution. He has used now occurs in all his cases one half; one and one half grain solutions beins, the dose employ of

The operations were i r harmorrhoids it tule strictures polypi ulceration ne colostomy and three an ers. The colostoms case was not suff ently anæsthetized with one half grain novocain t permit the operation to be completed without the illiti n of ether. One patient who was operated apon because of a great I all of pain in the rectum va given one and one-half grains of n vicain Uthough kept in the upright position within inc n mut > respiration had ceased and no evid n c of circulation could be observed Und r varou stimulants the patient again had good pulse and repiration but he died within twenty four hours I ost morten without regaining consciousness. Lost morten examination showed marked lisease of all the vit I organs which should have been suffici nt rea on for prohibiting any form of operation. With these two ex eptions the author's experience with spinal anaesthesia was completely successful and his convinced of its superiority in rectal operations.

Levis, B and Bartels L: Caudal Ansesthesia in Genito-urinary Surgery Su: 6 Obst 916 vail 202

This is the method of anesthesia proposed and instructed by Cateken and is based on the use of saline injections into the sacral canal suggested by Cathlin in 1701. It is a nerve blocking method of local anesthesia applied in the sacral canal using a combination of novocaine potassium sulphate and adrenalin as the local sedative fluid. At the time of the making up of the report the authors had used the method in 85 cases and with such success that they left justified in making the report.

This method is to be distinguished from that of spinal ansarhesia in that the soluti in a not in jected into the spinal canal. The spinal canal is separated from the sacral canal by the cuff of dura mater which closes down on the carda at about the first segment of the sacrum. An inject on of fluid therefore into the sacral canal does not reach up into the spinal canal. The object of the injection serves to obtund the sensibilities or amenitating.

the nerves issuing from the anterior sacral forumina that form the sacral plexus. One of the most important nerves of this plexus is the pudic, distributed t the bladder and prostate and other genitourinary organs. By an esthetizing this nerve an anzestheti condition of the organs mentioned is

secured.

Directions for preparing the solution are given and the authors experience with desage is detailed. It was found preferable t use larger quan tities of weaker sol tion rather than mall quan titles of stronger solution t binin the ansesthetic effect. It was f und that the pressure-effect f the anesth tizing fluid was strongly influential in securing success. From 50 to 90 ccm. f the fluid is now ber g used by the authors.

The method is particularly advantageou in the very debilit ted decrepit, and aged patients who require major work in genito-urinary surgery Prostatectomies done suprapubically removal vesical stones, and cystoscopies in hypersensitive individuals, have all been don with marked su

cess and comfort under this method of anaesthesia. The technique f the administration is described and illustrated in the original article. Measures for recycning untoward effects, such as introducing the needle int the spinal canal or into vein, are

described and suggestions given f r avoiding uch effects.

SURGICAL INSTRUMENTS AND APPARATUS

Bergaron, J. Z., Pilla Compression Forceps for Controlling Harmorrhag Following Tornell lectomy J [m II 4 9 6 lv. 5 5

The forceps devised by the thor for compression of the pillars after ton-il enucleation, consist f() a handl () lock (3) a goose neck shank, and (4) ompression tips. A compant forceps which has traight sho k is also described the tw t be used togeth th curved forceps to be pplied above and the straight forceps below The curved f resp. ar so con tructed that the han dl lays utald of th mouth, sufficiently t the ude t permit ork on the other tonsil or the aden ids bile the compression continues

SURGERY OF THE HEAD AND NECK

HEAD

Gray H. M. W. Observations on Gunshot Wounds f the Head. Brill M. J. 9 6 1, 46

The principles in the treatment of these wounds as deduced by Gray are as follow () Infected gunshot wounds of the skull and brain require more careful consideration and prompt ttention than similar wounds of any other part. (2) Sepsis can best be combated and prevented by early and complete operations. (3) Permanent disability can be prevented in most cases by the systematic removal of foreign material or displaced bone from the urface or substance of the brain whenever these are accessible t legitimat surgery (4) By these precautions the immediate results in the saving of life and more rapid restoration of function. when possible, are better than those obtai ed by more conservative procedures.

The presence of any foreign body in the brain may not cause immediate disability but sooner or later the brain is very pt to resent the presence of these bodies and untoward symptoms develop. Fragments of bone, clothing, metal, etc., should therefore be removed as soon as possible after the receipt of the injury The presence or absence of cerebral or cerebellar symptoms should not in the average case, deter the operator from the radical treatment of these wounds.

In minor injuries the lacerated scalp should be excised and sut red. Primary union usually results.

I depressed fra tu es of the inner t ble contusion of the brain is limost cert in to occur. The dena should be opened all such cases even when it is app rently normal otherwise in ries t the brai substance may be overlooked and scar tusue form which may cause future trouble. Furthermore the injured brain substance if allowed to remain untouched may become infected and cause abscess. encephalitis, meningitis. When wounds I the blood sinuses are present it is thought advisable to remove depressed fragme is of bone for two rea sons () Their retention may cause obstruction to the return of blood from some part of the brain or

(2) may lead t septi thrombosis. As t drainage of the brain, as a general rule this should be avoided whenever possible. The pres ence of definit pas, infected blood-dot of inaccesmbl definitely infected foreign bodies, or profuse coming would inducat drainage. Bacteriological examination of removed substances should be made and if strentococci are found the drainage should be maintained until these disappear from the dis-

charges or become very few in number

Several points are enumerated by the author () There may be m Itiple injuries, therefore the whole scalp should be shaved. () The force causing the injury usually results in local injury i jury by contre-coup has rurely t be considered. (1) Fracture of the inner t ble Imost always means injury to the brain ubstance. (4) 1 complete operation facilitates repair gives better immediate results and tends to prevent troublesome sequele more surely than an incomplete one (5) Death is due in pra tically all cases to the effect of sepais on the damaged brain (6) The aim in all operations should be to remove as much infected material and tissue as is feasible (7) For ign both 5 act delet it usly in four vays by his tillert in delicate brain substance favoring sepsis interfering with circulation, and cousing scar formation. (5) It is highly important to prevent scar to ue formation whither on or in the Frain. The nature of the injury the amount of sepsis the presence or absence of foreign bodies and the treatment employed ha e much to do with the am unt f scar formation

The routine of treatment is as at flows. On all muser in the patients scalp i shaved the wound thoroughly examined and two skirsgrams taken at right angles to each other and an exhaustive neurologial examination made. In aperi it is given and urotropine given. If the brain is exposed operation should be done at once and in no case should operation be post-poned longer than to days.

The majority of wounds of the scalp should be excised and the bone beneath carefully examined if no bone injury is found the wound can usually be sutured and primary union almost always follows:

Depressed fracture demands immediate exploration Some cases a libout injury to the external table may hav fracture of the internal table usually suspected from the location of a ounds or the chinical inidings. Where the dura is normal in specarance and the brain pulsates well it may not be necessary to open the dura. When the dura is muddy looking and the brain does not pulsate it should be opened up by means of a crucial locusion. The uscless brain material will usually evide.

An injury to the dura without foreign body or sepsia requires careful trimming of the dura the lost tissue being replaced by a piece of aponeurosis and the scalp sutured. Where a foreign body or scepsis accompanies the injury its windrawal is attempted and drains usually inserted along the track.

Injury to the blood sinuses can often be closed by the application of a small piece of aponcurous. The opening is carefully cleansed and the small piece of fascia then quickly applied

Lumbar puncture has given rehef from persistent headache in many cases but ordinarily no more than no com should be withdrawn I H Skills

Cook, P. S. Bone-Transplantation in Nose Deformities. B s B J gate xt 42

Three cases are reported in detail where bone deformities were corrected by bone transplants. The technique is as follows. A curved incision is made at the root of the nose and the skin dissocted free clear to the tip. The periorieum is then in "laed and raised. A piece of the funth is then inserted."

with its periosteum still attached and sutured in plife. The skin is sujured and the stitches removed on the fourth or lifth day. The nuthor laims very good cosmeti-result. I H Skirs

Kazanjian V H. Treatment of Maxillary Fractures. Br (M/J) 16 266

These fractures are usually compound and the treatment of the wound is very important but not related especially to the discussion at hand

The aim is to maintain a comparative initiability of the parts. All the available devices may not be sufficient to affect this condition when much bone destruct in its pro-ent.

The ordinary ase is treated by tirm ban lage with wring of the teeth is such is necessary. The care of the mouth is important and antiseptic douch es and applications are recommended. The most dreaded complication is hemorrhage. A slight our ing may be the beginning of a serious hemorrhage and should be carefully followed up.

Cole P P and Bubb, C. II Deformities of the Jaws Resulting from Operation or Injury B it M J 9 5 i, 263

In deformittee from operations in the upper jair conditions may be present which require one or more of the following procedures: (1) an attempt to separate the nasal from the oral cavity: (2) to restore the masticating surface and (3) to ristore the facal contour. The apparatus is usually made of vulcanite and is hild in position by aluminum pipe.

In simple division of the lower jaw a suitable splint may help in coaptation of the nds. When part of the mandible has been remo ed the lateral gliding shoes of tehn t are trooms nded. When

o e-half of the mandible is removed a modified Gunning splint may prove useful. J H. SELLES.

Weil, R. The Treatment of Parotid Tumors by Radforn. J Am M Ass 9 5 ker 38.

Although recent literature contains accounts of partiel tumors (avorably influenced by radium, yet as these tumors are of different types and no information has been given as to the microscopic structure, definite ded ctions cannot be drawn as to the particular type or types of paroid tumors which are suitable for radium treatment. The case mow reported by Well has reference to a tumor of this kind of seven years' duration, which was histologically examined and classed as adeenoid cystic cytihelions. The general type of the tumor was that which Billroth named cylindrous.

The treatment consisted of the insertion of radium into the tumor for six weeks at the end of this period it had disappeared and after an interval of almost two years there is no sign of recurrence

HOLLE E. POTTER

Morestin H. Repair of Losses of Frontal Substance by Means of Cartillaginous Transplants (Réparation des pertes de subassace du frontal à l'aide de transplants cartillaginous). Buil et sein Sec de chir de Per. o 8 nil, 411

Morestin reports the operative details of two rather extensive breeches in the frontal regions repaired by cartilaginous transplants. The technique is relatively simple and the results in such cases are constantly favorable. The cartilage is better taken from the subject humself but it may be better taken from the subject humself but it may be bettered from another operated subject.

In Morestin's first case there was an osseous loss about the size of a five franc piece in the right frontal region between the cychrows and the root of the nose. After a series of plastic procedures to restore the symmetry of the parts, the b eech was finally filled with cartilage taken from another patient.

In the second case where there were also very extensive losses and the right eye had been cuscle ated, the repairs were effected by material removed from the region of the seventh and eighth costal cartilages of the patient's right side. In both cases excellent results were obtained.

The work is very delicat as it involves recon struction of the interior part of the upper orbital areade and the frontal region corresponding to the root of the note.

W. L. BREGGER

Landry L. R. Intracranial Homorrhoge Du to Traumatic Rupture of Arteria Meningica Media; Report of Six Operated Cases with One Death. Sould M. J. o. 6, 1 cr

It is estimated that 90 per cent of meningeal poplexies prove fatal if unrelieved surgically while of a large series of operated cases 67 per cent recovered, a percentage which would have been much larger had it been possible to secure intervent in before the onset of medullary symptoms. All statistics favor operative relief those of Bergmann being the most convincing, so successes in 22 operations. The great majority of extra dural hemorrhages occur in the lateral aspect of the skull, particularly in the temporal region, those of alight degree not causing symptoms of compression. Ashurst found that a clot between the dura and the bone equaling one-twelfth the capacity of the cranium will prod ce come and death in a few bours. The most common source i the bleeding is the torn anterior branch of the middle meningeal artery Occasionally the hamorrhage has been sought for on the opposite side while in reality it was on the same side as the existing cerebral manifestations at the extremities. The author believes that compression of the opposite side accounts for the collateral paralysis.

Usually the patient is so stunned from the injury that a degree of unconaciousness is produced, from which he recovers only t how evidence of cerebrai disturbance headache possibly vomiting and stoper. This free interval was marked in four of the author; seases but was beent in the first two. In the clinical picture medullary symptoms are invariably present the blood pressure is high robies show resurration is labored that it is

high pulse slow respiration is labored later it is if the Cheyne-Stokes type and finally the paralytic stage of compression supervenes

Compression from any cause must be removed, whether from depressed bo e epi hemorrhage. If given proper trention the most terrible injuries of the skull will go on to a good recovery. It is asie to say that in any serious cranial injury in which unconsciousness has been p esent from the first subdural bleeding is t king place. In localizing the anterior meningent artery the method of Kronlein is the most acceptable At the pterion the artery is found passing forward and this point is located by dropping perpen dicular from the bregma to the middle of the sygoma, then drawing horizontal line back from the external angula process at the juncti of these two lines is the Sylvian point the location of the pterion. However Il methods of measu ement have lost their importance as the surgeon of today explores through a large perture and not by trephining. Usually the injury t the cranial

vault is the best guide to the seat of hemorrhage.

The author advocates immediat exploration and decompression in doubtful cases, as such an operation adds no more risk to lift and often prevents at fall outcome.

E. Vanstrova.

Gossat A. Cranioplasty by Cartilaginous Flap (Cranioplastic pur voict cartilaginets: Bull of mem. See a chir a Par. 9 6 xill, 441

Gouset reports 3 cnaes of crantal osseous breeches repaired by cartilaginous flaps. Whereas, Morestin, who is the originator of this method use II yeals himself of several pieces of cartilage in building up and closing the breech Gosset prefers to use one sincle piece. He thinks this gives better result in

combating pressure from the brain and in the rre vention of cerebral herma W L BRE, WAS

Types of Hydrocephalus Their Frazier C. H Differentiation and Treatment 1 = J DChild to 6 1 of

The author suggests a new classification having a physiological background with direct clinical application

- 1 Hydrox phalus obstructions
- 2. Hydroc phalus nanabsorptus
- 3. Hydrocephalus kypersecretitus
- Hydroc phain occulins In hydrocethalus obstructions there is mechan nal obstruction to the natural drainage of the cerebrospinal fluid from one or more ventrales into the subarachnoil space where the absorption takes place. This obstruction may be due to a congenital defect su has absence of the aqueduct of Salvius or as is more frequently the case it may be the result of adhesions from a pre-existing inflammatory lesion. If the aquedu t of Sylvius is lacking or closed by adhesions there will be a lilatation of both the third and the lateral ventra les while a closure of the foramen of Munro would rause merely an enlargement of the lateral ventri.I on the affected ade. If as is often tru in cases of high-grade but evenly-distributed hydrocephalus the passage of the fluid through the foramina of Magendie and Luschka is blocked there will be a general dilatation in which all the ventra les par
- In hydrocephalu nonabserptus absorption is d laved or defective as has been proved by the phenolsulphoner hthaleir test. Whether the restricted absorption is to be attributed to () the cutting off of part of the subarachnoid spare by adhenous (2) a toric substance in the fluid which prevents its absorption by the venous channels or (3) whether it is fue to an abnormal condition of the agents which transport the fluid to the venous dreulation is still a matter of conjecture
- 3 By a process of elimination and by a careful consideration of the normal physiology of the cere prospinal fluid and of the possible changes under abnormal conditions the third type with apparent excessive accumulation of fluid has been attributed to hypersecretion-hydrocephalus hypersecre tirus. Since it has been conclusively proved by morphologic and histologic studies of the choroid plexus by chemical analyses of the fluid by a study of the effect of chorold extract on the secre tion of cerebrospinal fluid that the cer-brospinal fluid is the secr tory product of the choroid gland it would seem logical to suppose that a pathologic ondition of the gland itself or a toxic substance in the fluid coming in contact with the plexus might bring about a hyperactivity of its cells

4 The author includes in the varieties of hydrocephalus a fourth type for which the term And o r phulus occultus has been chosen hi h though paralou at is otherwise appropriate. The condition thus designated or ur usually in childr n though occasionally in adults and is characterized by excess of fluit in the ventricles based systemse and sometimes throughout the subara hawid space without there necessarily being any increase in the cranial dimensions Symptomatically this condition may be more lowly alle I to tumory but from the point of view of treatment it properly belongs to the oroll my f hy frocenhalus in that the essential feature is an x essi e accumulation of c rebrospinal fluid in the ubara boold pa e

The clinical tests may be ummarized as follow

First examination Lumbar min ture

Withdrawal of r ccm of er-brostinal fluid Attach a cm record vringe till I with a cm neutral solution of lye

Trauma lues tuberculosis sept meningitis brain tumor and chronic alcoholi m may be assointed ith it while tubercular meningitis n as I ad to fatal hydrocephalu

The author outlines the anatoms and this ligh

of the ventricular system and discusses the sources of origin of the cerebrosynial fluid. By means of experimental blockly off of the ventricular cavities and stimulation of the chorold plexus the latter have been shown to be the chief origin of the fluid Likewise other experiments have shown the egress of the fluid to be chiefly by means (absorption into the stratchnold villi and ventros sinuses. Flence, an increase in the cerebrospinal fluid may be due t (1) and overproduction by the chorold plexus of a distance of the control of the cont

That certain types of this condition (choroidor rhees) may be of toxic origin seems probable from the effect of the injection of certain drugs or extracts, since brain, plexus, or pitultary and also muscarine have a stimulating, thyrold a depressing effect upon the secretion. As regards pathological conditions producing symptoms of hydrocephalus. the uthor points out that large posterior fossa tumors are sometimes without signs of increased fluid tension, and that the important sign of choked disk may not be due directly t—the tumor itself but to the hydrocephalus, causing infiltration of cere brospinal fluid along the optic nerve sheaths and compression of the venous return from the retina. In essential hydrocephalus with no pathological obstruction, vicious circle resulting from ex cas obstruction, accumulation of fluid in the disterns magna pressing on the veins of Galen which causes increased intrasinus pressure and depresses absorptive action is responsible. Forcing upward of the midbrain and plugging of the tentorial opening may also be actor

The practical results of obstructive conditions being a cutting off of the secretory from the absorptive systems, it is unlikely that thyroid extract o other therapeutic substances will be of benefit and evidently a communication between the syst ms must be established. The author mentions the various operations devised for this purpose, and recommends the method of von Bramann as the simplest. In this a ventriculostomy is per formed by the passage of a bl t cannula by way f the I ngitudinal fissure and puncture of the distended lateral ventricle. The continual escape of fluid into the subarachnoid space equalizes the pressure and co ditions approach normal. This pressure and co ditions approach normal. operation is indicated both in hydrocephalus of the obstructive type and in emential choroidorrhora in infancy, before cerebral destruction ha occurred. The technique of the operation is outlined F flures may be due t closure of the ventriculost my opening. HORACE BEGGET

Jacob, F. M. Glioma of the Cerebelium with Metastases, J. Hed. R. ris. 95 vii. 95. Jacob reports the case of a young adult givi g a typical history of brain tumor extending over pernod of two years. The autopsy showed a large glooma f the cerebellum which had extended into and oblit rated the fourth ventride and occupied most of the central white matter of the cerebellum. Smaller masses of simila character were distributed upon the ependynan of th latent ventricle the central canal of the spanal cord and th leptome in ges. All of these masses were very cellular, unencaprolated inhitrating and to all microscopical poperance milignant in character. Gind-like

ppearance mulignant in character Gland-like of rosette structures were tooled in many parts of th turn is. The masses in the ventricle were discrete and had nodular papilomatous structure but the pla mater of the cerebrum, cerebellum, and cord conduited a patchy growth of glomatous tissue extending over a considerable area involving much of the surf ce of the brain a d orol. He found no masses in any organs outside the cranial and small causties.

From his study the author draws the following conclusions

Although glomata of the brain do not invade blood and lymph hannels or form metastases in distant organs, they do form metastases in the brain and cord by means of cerebrospland fluid. The reason for this, he belleves, may be found in the fact that glis cells are highly specialized and cannot grow when removed from their natural surroundings.

Even though gliomata of the brain d not metasizative to other organs, many of them, the author thinks should be considered histologically malignant or at least locally maligna t on account of their poetrol indirection, rapid rate of growth and the embryonal character of the cells.

GEORGE E. BEILBY

Grey E. G. St dies on the Localization of Cerabeliar Tumors. 1 Surg. Phila 9 6, 1vill, 29.

lotwithstanding the comprehensive literature which pertains t discuses of the posterio cranial force, the significance of the position of the bead and of suboccipital discomfort still remains uncertain. The autho has enrefully analyzed the symptoms in 60 certified cases of cerebella and extracerebellar tumors from Cushing's neurological service in an attempt t determin a consistent relation between the position of the head and the location of the tumor About 40 per cent of the cases with cere bellar tumor showed some chang in the position of the head while only 7 per cent of the cases with tumors attrior to the cerebell m showed any unusual attitude, and in each of the latter cases the change was alight. The tilting of the head or its rotation in patients with symptoms pointing toward an intracranial tum is very suggestive of b-tentorial new-growth. The attitude has no par ticular algulficance in localizing the lesion in one side r the other of the cranial fossa.

Backward retraction of the bead occurred in 8 out of the 60 cases and typical opisthotonos att ks appeared in 2 of these cases. As this conditio

In the opinion of the author all such cases abould be removed even if it involves the ligation and excision of the carotids, and no attempt should be made to dissect the tumor free from the vessels unless it is only loosely tiached to them.

Lerich 1 Resection in the Case of Projectile Wornds of the Neck (Resection dans les plairs du conde par projectiles de guerre) Bull- et mêm Sec. de chir d' Per 0 6 viil. 4 6

Leriche reports the details in the case of four resections of the neck which be has performed owing to injury of the articulation. Two of these were done within a few days after the injury and the other two were done considerably later. Excellent results were obtained in the lat cases, but in the other cases there were defects of lateral movement

Ollier's technique was followed.

In submitting Leriche' report Quénu considerathat there are three categories of neck rescutous (1) pumilitve, practiced immediately or in the first days after highly and before there is any microtoo, () early secondary made within a few weeks of injury and Quiat secondary when the acut usag is passed and when only a satulous trajectory in present or even cicatrization is effected. Quému thinks that whenever the articulation is 1 of eqprimitive rescellon is called for He reports some cases under each category observed by him with particulars of treatment and results obtained.

Koch, W. F. Th. Physiology of the Parathyroid Glands. J Leb & Clin Med. 9 6 i, 200.

HARRY G. SLOW

glacial drifts.

After consideration of ductiess glands in general and the parathyroids in particular Koch endeavors to elucidat the obscure mechanism of the activity of these glands.

The behavior of the parathyroidectomized dog may he says, coboide with either of two distinct types of symptoms, or with a mixture of these types, in which either may predominate. In one type the dominant feature is over-excitability in the other under-excitability. In the former toul convulsions are characteristic in the latter we observe peculiar muscular facedity and a general depression of the nervous system. In either case a pathological condition develops within a few days after removal of the glands and proves fatal within two to ten

Up to the present only one fact which contributes

to the explanation it this pathological process has been advanced it is the discover by MacCallum that the urines of parathyroidectomized animals contain excessive quantities of calcium and that when calcium salts are injected intravenously into such animals the tetany is immediately controlled It was shown by Beebe and Berkeley that injections of other salts have a similar though not so marked an effect.

Koch recently found that when the tetany had become incontrollable by injections of aqueous salt solutions the kidneys had become so patholog ical as to be unable to functionate normally one of the effects of such intravenous injections is difference it may be assumed that one of the bench tall effects of the aqueous calcium injections depends apon increasing the work of the latines, and thus the detorication of the blood. If on the other hand the value of calcium d pends upon the increasing or maintaining of a certain reaction of the blood the acid radicals are here the important in this. They present two possible modes of a truty the simple neutralization of basi ubstan es excessi e's elab orated within the body or the destruction f uch ubstances as are capable of produring he t tank

There are then several indicate in subat the tetamy fiparathyroid insufficiency is due to an in our attorn namely that it is subdued by in reased durests and by the new ratication (force has inverted destruction of a torin by acidity. That the rigin of the happy thetical tore substance is the body it self that it is useful and not torough the presence of the parathyroid glands, and that it is not red through the glomerulus of the ladney point to a lub tance hormone like in nature and there is every unstable.

chemically

In the effort to ascertain the present e and identity of such a substant e the urines were ellected separat ly from 4 parathyroidectomized dogs Especially designed ages were used to avoid facul contamination. The urines were intered and evaporated to a syrup by an electric finant at a tem.

The auth r on lufes as follow. The imilants in the behavior of the parathyroidectomized dogs to that f the non-americative aurinals treated with the ubstan e isolated from the utine is turther in liciation that this substance is responsible for the symptom-complex of parathyroid maintineary. The data therefore justifie the following conclusions:

1 mewhere in the body methyl yanamide is generated

2 This substance has a phy iological value in normal animals

3 After parathyroid extirpation the substance a cumulate to touc quantities and is responsible for the death of these animals

ALBERT ERRENTRIED

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Perreau II Penetrating Wounds of the Chest in Warfare Med Pre 1 of C r 1916 cl, 100

A penetrating wound of the chest requires immediate immobilization of the chest. The diagnosis should therefore be made as soon as possible and doubtful cases should be treated by immobilization also as it can do them no harm and may even expedite healing. The early diagnosis is greatly assisted by the roentgen ray.

The immediate immobilization of the chest is necessary to avoid severe complications. Among these complications may be mentioned (1) Embolism which may be caused by any sudden movement

even after a considerable lapse of time and which may prove rapidly fatal. (2) Pleural effusion is very common and ma change to a purulent fluid (3) Subcutaneous emphysems may occur either local or more or less general. (4) Bronchopneumonia and hamorrhage are tare complications In order to lessen the liability to these complications immediate absolute and prolonged immobilization is necessar.

The conclusions reached by the author are as follows

I An early diagnosis should be made by the aid of radioscopy wheneve possibl

z Immédiate absolute prolonged immobilization should be ordered

3. The patients should be kept on a water diet for the first two or three days, not allowing them to raise the head to drink

4. Such patients should not be transferred until after a formight's immobility

5. During the first four or five days a daily dose of 10 ccm, of camphorated oil should be given. 6 Except when absolutely necessary no attempt

should be made t remove intrathoracle projectiles. 7 Prompt, wide opening should be resorted to to give issue to early copious purulent effusions I H. Skitters.

Boothby W M Gunshot Wounds of th Thorax. Beste M & S J ched 0 6 175.

The author discusses his observations on a cases of thoracic injurses out of a total of 441 wounds f all kinds treated in the Harvard Unit. The cases bserved fortunately included examples of most of the important thoracic lesions which reach hospital

cure Hæmoptysis was present in nearly all of the cases. In some it was very slight lasting for a short time in others it was present for many days. It was more apt t be present when the lesion occurred from the larger and irregularly shaped missiles.

Hemothorax is a complication which arises from injury to blood vessels belowing to the general rather than to the pulmonary circulation such as the intercostals, the internal mammary arteries and veins, and the azygos veins. These vessels are not surrounded by muscular tustic hence the tendency to hemorrhage from them. An additional cause of harmorrhage is due to the f ct that the blood shows no greater tendency t dot when it is in contact with the endothelial lining of the pleura than it does when in contact with the endothelium of the blood-vessels. Toeumessen found that at first the fluid was dark red with a cell count essentially similar to that of blood b t with fewer red cells and a higher percentage of cosmophiles. The fuld had no tendency t clot in the pleural cavity or when withdrawn. When the vessels had finally stopped bleeding the fluid became brighter red with a decrease in the n mber of red cells though the white cells remained the same. The percentage of cosinophiles gradually increased, as m ch as 70 per cent. The fluid while showing no tendency t dot in the pleural cavity clotted when withdrawn. During the stage of absorption the fluid became less hemorrhagic and at times almost entirely acrous. At this tage it man lost its clotting power when withdrawn from the pleural cavity

Penroldt states that at first the blood is defibrinated, and later as pleuritic irritation develops, an increase in leucocytes occurs with the development of a new blood-clotting substance from the pleural endolethelium. When the fluid remains long enough in the pleural cavity this dot producing substance gradually disappears with the pleural irritation. The presence of the cosinophiles is due to some local cause as they are not present in increased n inher in the circulating blood.

Sauerbruch has pointed out that bleeding from lung timue, or the vessel of the pulmonary circula is of short duration. The lung tissue itself seems to possess a hamostatic action the early clost up of blood is also favored by the low pressure existing in the pulmonary system of vessels and lastly the vessels of the pulmonary circulation are urrounded by a loose tissue which on injury contracts d wn on the bleeding vessel.

The most important principle in the treatment of hemorrhage is absol to rest which favors low blood-pressure and clotting Since it has been shown that lat bleeding is pt t occur in from eight to fourteen days after the injury t is better allow a period of rest of two weeks to clapse before extended transportation is adertaken.

Out of 84 post mortems beeved by Bradford and Elliott at Boulogne in which death resulted from chest wounds, 60 had effusio of blood in the pleural cavity 3 d ed of complications like puru lent bronchitis paraplegia, or abdominal lessons 46 died from ha-mothorax, in 18 of which infection was present Death from harmorrhage resulted only in one case.

In one group of 168 cases of higmotherax treated chnically 114 were steril and 48 had such large effusions that it was necessary t aspirate. Twenty eight infected effusions survived after resection of rib Twenty deaths were due to infection.

In a second group of 60 cases 68 remained sterile and I these a required aspiration, to cases were infected and survived resection of rib. Out of r deaths 16 were infected. There was one death from simple hemothorax.

The foregoing statistics abow the dangers of infection in hymotherax. The authors input on rest of three days after the receipt of the wound The patient is then taken as rapidly and comfortably as possible to a place where surgical work may be undertaken with safety

Asperation to remove part f the fluid and to thereby hasten absorption should not be delayed unduly since the presence of hematoma favors the formation of dense pleuritic dhesions with time The military surgeon is often prevented from operating with safety in field practice but whenever he commands his environments for aseptic work the rule of aspirating early rather than lat should be practiced. The presence of increased temperature which prompts aspiration is not always the result of sepsis. The rise may be due t absorption of fibran and it may be further aggravated by respiratory embarrassment and mental worry The rule is to aspirate in all cases of irregular tem perature and to practice thoracotomy wheneve pus is found

When aspiration becomes necessary the amount of fluid to be withdrawn is a debated point. Sauer bruch believes that this should not exceed so to to ccm. If too much fluid is removed the intra pleural pressure vill be lowered and there will be a tendency to recurrent hemorrhage. In order to avoid the danger it is better to aspirate with a simple aspirating needle to which is connected a rubber tube 30 cm long the whole of which is filled with sterile water and the distal end immersed in a basin of sterile water. This method produces a suction equivalent to the difference in the level between the surface of the water in the basin and the level of the needle which may be varied up to 30 cm. This amount of suction can be pra-ticed with safety. The method is less risk; than the use of an aspirating bottle and pump with which a negative pressure of considerable amount may be produced by the pump.

In pneumohemothorax air present above the level of the liquid generally disappears rapidly unless there is a permanent communication with a bronchus. The latter adds to the danger of sepsi and when sepsia ensure thoracotomy is no order.

Cardiac injuries are treated by absolute rest and morphia given in sufficient quantities to keep the patient drows. Immediate operation is rarely possible under field conditions at the front. The service that preceded the Harvari Linut removed a builtet by operation that lay free in the peri ardial cavity. The patient recovered in spite of an empty emp following the operation.

All cases with a patent opening in the pleum become infected. The frequency of infection depends largely upon the character of the mustle and the condition of the patient is skin and clothes Infections are more frequent in 1 roportion to the distance from the front. One observer kin empyema in 3 out of 28 cases another 2 into 4/3 cases. Tuflier saw infections develop most frequently after skill wounds and when a foreign body was lodged.

Some observers point to the resistance of the pleura to infection as shown in repeated instances of infected external wounds leading to the pleural cavity in which the pleural wound closed thus warding off infection. It is generally agreed that the pleural membrane and the extrapleural birous tissu are very resistant to the passage of infection from the extrapl ural to the intrapleural surface. Nevertheless care should always be taken not to open the pleura in asses of large septic himatomata that develop extrapleurally and which are not connected with the pleural cavity.

When thoracotomy becomes necessary it should be done at the most dependent part of the cavity and the opining should be large enough to admit the hand for thorough exploration and to remo e foreign matter. Such a procedure wards off cm pyems and enables the operator to remove bedged missiles embedded in lung tassue near the surface.

musiles embedded in lung tusue near the surface.

The author concludes his article with the following summary

I Intrathorace hamorrhage is most likely to cease when the patient is absolutely at rest therefore he should be kept in bed (under morphia if necessars) at the first a milable station 2. Improms rapidly developing suggesting pneumona with marked dyspin as are probably due to the production of a large hampthorax or a pneumothorax. Such cases should be aspirated and sufficient for a superative pressure within the thorax by the use of an apprairing bottle. I simple needle with rubber tube to mit long alled with sterile water and the open end immersed in a basin of sterile mater will produce as great as ut to as a till safe to use. With such an apparature as much fluid can be withfrawn a will run out of its own as ord.

3 after thre days the danger of infection exceed that of hemorrhage. Therefore it the patient is it in a place equipped for diagnosing and operating for mpx ma h sh uid be removed to the neurost hospital so "quipped and kept there for at least two weeks."

4 Whenev T the patient presents an irregular elevation of temperature exploratory aspiration with a small hypodermic syringe armed with a long needle of large bore should be performed.

5 When ver the pleural fluid is tound infected a long thoracotomy opening should be made and free drainage instituted

6 If the patient is in a dangerous ondition prolonged search for the presence of a foreign body should be deferred. However all foreign matter should be removed as soon as possible in order to hasten the final closing of the wound.

TRACHEA AND LUNGS

Villeon, P de la The Surgical Extraction of Intra pulmonary Projectiles, Superficial and Deep, Under the Screen by Simp! Rapid, and Certain Means (L'extraction operatoire des pro-jectiles intrapolimonaires, superficiels et profonda, sous l'ecran, par un proceti simple rapide et sur) Bull. Acad de suid Par 9 6 l'exv 75.

Thoracoppeumotomy for the extraction of intrapulmonary projectiles has been practiced by the

author with uniform success.

He also uses a method much simpler and more rapid which was carried out successfully in so cases The principles of this new procedure are based on the method for using the radioscopic screen for the extraction of intrapulmonary projectiles, which was originated by M uclaire. Villeon technique is different from that of Manclaire in that

it allows of the extraction of deep as well as super ficial projectiles.

The projectile being located by \ ray the anothetized patient is placed under the screen, in dorsal or abdominal position, according t the nearness of the projectile to the anterior or posterio surface of the lung. The projectile makes a shadow on a point of the thoracic parieties. Two or three finger-breadths away in the intercostal space by menns of tenotome or a fine blade a narrow 5-mm. buttonbole incision is made in the skin. Through this incision is introduced a closed forceps (long lenn, long Kocher) or an old style forceps for the extraction of bullets. This forceps passes with difficulty into the narrow buttonhole inchion, and following line oblique to the normal of projection, leads directly to the projectile. It turns aside before it the intercostal fibers, grazes the upper border of the inferior rib (to avoid wounding the yeasels) and always closed, goes through the parietal pleura, then the visceral pleura it then enters the parenchyma where by a gentle handling it is pushed up to the projectile and touches it.

At this moment the X ray operator I tervenes for the second time to ascertain whether the forceps is in the right place if t to correct the direction The forceps touches the projectile and mobilizes it The forceps then opens gently catches the fragment and extract it as the opening through which the forceps enters the skin incision is very small on withdrawal not particle of air enters bence no pneumothorax result The operation lasts but a few minutes, frequently only a few seconds, in difficult cases, 5 t 7 minutes in simpl or typical cases, 4 1 60 seconds With one suture the b tton hole incision is bermetically closed immediately after the regular dressing is applied. The patient is returned t bed, and receives hypodermic injection of o os og of morphine to avoid excitement upon wakening and t insure respiratory quiet. In cases of large projectiles, the skin in cision is enlarged only when the f reeps with the projectale in its blades reaches the skin opening, which can be enlarged as required

In cases of deep projectiles (8 t 12 cm) the auth employs n old model long bullet forceps.

This sort of instrument tion has given satisfactory results in 6 cases, nd only in a very few cases did any air enter the pleural cavity or slight subcutaneous emphysema result incidents without consequence, all of which the uther booes to avoid in the f t re by using forceps (on the style (Grunwal) which he is now constructing

It sometimes occurs that whe the lung is free of all attachments, the forceps does not penetrate the parenchyma at the first tempt which occur rence permuts of invagination and depression. Slight force may be safely used on the visceral pleura in order to enter the parenchyma. The organ resumes its normal shape and the seizing is easily done. The post-operatory sequels are of extreme simplicity Slight blood expectorations for two or

three days thereafter are of Importance

The day following the operation, the patient may sit up in bed. The uther patients left the bospital on the fourth day in a few serious cases on the eighth day. All cases were devoid of post operatory pyrexia. The fever curve remained at 37 C. All symptoms disappeared in four weeks. The autho never uses costal resection and never

has been troubled with pneumo- or hemothorax. This technique has been used by the author in 6 cases, withdrawing 17 projectiles 9 superficial

In the small gut resection has a higher mortality than suture but this is doubtless due to greater lintual injury among the resected case. The actual function line in the resected case arely gave trouble. There cases of obstruction were due to non toxic paralysis. Resection is to be used instead of suture when the saving of time is an object. Continued edges were found to heal yell and without slough after suture. The solders small intestine is usually empty—the converse is true of the large gut.

Of 33 stomach wounds only 11 were uncomplicated by other lesions the anterior wall was most often in olved anteroposterior wounds were not commonly f und extravasation of stomach contents vas fairly frequent depending on the time of the last meal

Of 7 fatal cases of stomach mynry uncomplicated by wounds of other hollow viscers 4 died as a result of primary hamorrhage. The author dwells on the scriousness of wounds of the epigastric region, and he favors operation in all cases.

The absence of injury to the spleen in stomach in juries was notable and it suggests that such injuries seldom live to reach surgical care

In the large intestine the mortality was 60 per cent as a result of peritorities or perhaps more frequently septic infiltration of the retropertioneal tissue. Wounds of the transverse colon are more apt to be multiple than those of the other divisions of this gut

Considering the extent of the injury the wounds of the great gut are much more fatal than those of the small gut no doubt due to the greater toxicity of the great gut contents

Most of the injuries of the liver were explored for

hemorrhage A good many cases might have reexceed without operation

It is suggested that a good man) spleen ases recover spontaneously and that it is only when the vessels are from that bleeding is excessed so seem to be not uncommonly injury at the same time while the stornal health ways secarcis.

Walker M H Jr and Ferguson L M Peri toneal Adhesions Their Prevention with Citrate Solutions. 1 1 halfs 3 0

The authors have performed mor than 100 experiments upon rabbits with the idea of decovering the exact effect of hypertonic solutions of sodium citrate and sodium chloride upon the peritoneum and upon peritoneal adhesions. By careful histological examination of sections made of a the ions taken from one to fifteen day, after operatin in they find the pathology of adhesion formation is simply the process of healing as found where et tissue has been destroyed.

Fir t an inflammatory explate of strum and blood is poured at and out kly coagulates. This exudate is mposed of fibrin with a few red and white blood-cells in its meshes. The adherent abrinous exulate is the frame, ork upon which the fibrous adhesions are built. Within 48 h urs the connective tissue and endothelial ells at the base of the adhesion begin to proliterate. Pibroblasts and new blood vessels appear very rapidly until at the end of a week the adhesion is made up of a fairly dense fibrous tissue containing a moderate amount of blood vessels with no inflammatory As time goes on the vessels become exudate less numerous and the tibers of the adhesion appear to rea h in among the muscle-bundles of the muscle coat of the bowel or of the abdominal wall as the case may be Meanwhile the endothelial cells of the peritoneum have proliferated and covered the abdominal surface of the adhesion. The final appearance of the adhesion is simply that of a dense scar tissue band covered with pentoneum

As the result of their experiments the auth is conclude that hypertonic citrate solutions do under certain conditions prevent peritoneal adhesions after laparotomy. The best solution is sodium citrate 3 per cent and sodium citrate 4 per cent and sodium citrate 4 per cent and sodium citrate 4 per cent and sorting in the folial peritoriones a sufficient amount of solution should be introduced into the abdomen to bathe the whol peritoneam (500 to 600 ccm.) and smaller amounts would be of little value.

The nuthors have not used the solution in human surpey, and suggest that the question of shock must be considered and determined by actual tests in the operating room. They believe that if gaure packs used to wall off the intestines are well in circuit solution much fewer adhesions will result. A the sions cannot be prevented in the present of infection by any known method. Large areas of denuded

peritoueum should be covered by plastic operations, for the larger the demoded areas left, the greater the likelihood of adhesion formation. Iodine abould be used with great care as very little if allowed to touch the bowl causes masses of dhesions. Dry gaure should not be used inside the abdomen.

Pope, S. The Prevention of Peritoneal Adhesions by the Use of Citrat Solution. Ass Sarg Phila., 9 5 bill, so;

Two years are the author advocated the use of sodium citrate with sodium chloride in solution for the prevention of peritoneal adhesions. His reasons were based upon experimental a rk done upon rabbits. Since that time with Wallace Terry he has used a solution of cirrate of sods per cent with sodium chloride per cent in some 400 ab-dominal sections. In about 20 cases from four ounces to a pint of this sol tion was left in the abdominal cavity. In the other cases, the gause pads and sponges were moistened with the solution. There is no evidence to show that the liability to infection is increased by this treatment, but on the contrary where peritonitis is present, a marked improvement seems to have occurred. The quantity of sol tion was left in the abdominal cavity of such cases as general post-operative dhesions acute obstructions, pus-tubes, colectomies resec-tions, and tuberculous peritonitis. The abdominal wounds show more oosing during closure in these cases, but in no case was there evidence of post operative hemorrhage or failure of union. procedure causes pain and partially rouses the patient so that it has been found expedient to have the incition almost closed before introducing the liquid. Ten of their cases have been reopened so that the benefits could be judged by inspection. The purpose of the citrate is to abolish excessive fibrin deports with subsequent adhesion formation as it will not prevent inflammatory repair GATTEROOD.

Bayne-Jones, S.: Eventration of th Disphragas, with Report of a Case of Right-sided Eventra tion. Arck Int. Mat., 9 5, xvii.

The author reports a case of eventration of the right side of the disphragm. This diagnosis, made from physical examination, was the first of its kind determined during the life of the patient. The clinical impression was confirmed at operation.

The author has collected from the literature 45 cases of eventration of the diaphragm. Of these 5 were right-sided and 4s were left-sided lexions.

In the differential diagnosis between eventration and allied states, the author points out difficulties, particularly with regard to the differentiation from hemia of the diagheragm. He believes that no single method is capable of establishing this differentiation, but the combined methods render the diagnosis reasonably certain.

He summarises the various etiological hypotheses,

showing that the weight of evidence is in f vor of the opinion that the disease has a congenital origin. Grozor E. Birtay

GASTRO-INTESTINAL TRACT

Dewis, J. W. Alds in th. Diagnosis of Surgical Conditions of th. Stormach with Especial Reference t. th. Characteristic X Ray Appearance of the Syphilitic Hour Glass in Contrast t. Those of Simple Uters and Cancer Load M. 4. J. 9, 5. 56

The author believes that the greatest single aid in detecting canner of the atomach and in differ entiating this from ker is the V-ray. It is not easy to differentiate cancer from syphilitic uleer of the atomach, and even the V-ray may fail t detect cancer near the cardia. In the lower two-thirds of the stomach the V-ray examination ought t show cancer in every case I properly done and correctly interpreted and in the majority of cases it will detect cancer carlier than clinical methods.

On the other hand to determine whether cancer of the atomach is surgical and when inoperable, while th 'N ray is a valuable and the chief means are the ordinary methods and the sperene e and judgment of the clinician. The a thort thinks that surgery should be the treatment in all early cancers of the stomach but that the reverse is true in ulcer of the stomach and d oden m scept where there are acute perforated where.

Regarding chron ulcers whilst some extreme intensits are so convinced of the probability of ulcers healing that they would persist in the medical treatment of practically all ulc n, yet it does not seem likely that an ulcer of the stomach or dwole num with a lattory of theraly years dura tion can be cured with month or two of medical treatment of any kind

Chronic ulcers of the stomach become surgical under these coodinous when there is droude pyloric obstruction not elleved by medical means when there is permanent hour-glass contraction in the cases where pain and distress, sour regurgitations, and intractable dyspepsis do not yield to treat ment and faulty when there are severe hancortairs.

In syphilis of the stomach the first cle is a history of infection confirmed by the Wassermann test and the \ ray Th \ ray is most valuable in a differ entiative test Pictures of yphilus do ot show the moth-enten appearance of cancer and there is m ch more involvement of the stomach well than in simple ulcer But th characteristic point that differentiates syphilis from cancer and simple ulcer is that in syphilisic bou -glass stomach a long regular isthmus is seen, at each end of which the walls of the stomach rise more or less abruptly o dumbbell like This is in contrast to the sharp incision of simple ulcer hour-glass with practically no isthmus and the picture differs quite as much from the cancer bour glass with the infiltrated walls of the stomach aloping irregularly away from the con HOLLES E. POTTER. stricted portion.

Squires, J. W. Roentgen Ray Diagnosis of Gastric Lesions. V.) II J. q. c:

For the purpose of roenty n ray stuly the author divides stoma h lesions into two grups. The first includes tumons through it alheir a and syphilis lesi n which provides the stoma horizon. In the scindler up are included actual simple ulor and conjustic time he stoma horizon. The he so not grup defects only in the product of the horizontal product is made and the stomach the state of the stat

In early car in ma the rall graphi nu lings are very similar to thise in uler in that this stage it is impossible to determine by the Nav whether or not malignant degen ration by a worre? From an Xray standpoint however the important line of division is not between beingiance in malignance, but it determine which it is lesson has advanced sufficiently to be more a surgical case. This stage is determined by the production of permanent defects in the continuous about ratios and interruption of normal periodic observation of gastric ulers in the precauser in stages as on its early recognition depends sur es full treatment.

Radiograms are taken immediately after a test meal and every half hour atter or even m re tre quently until sufficient data are obtained. This is

followed by fluoroscopi examination

The disgnosis I gastric arctinima requires a very carful consideration of the radiographic and fluoracopic observations. The characteristic indings in order of unportaine are 11 illihing dietits (2) absence of peristalists in part involved (3) mobility (4) superimposing test (3) pain at site of filling defect (thours-copic) (6) changes in the pylorus (7) residue and (8) advanced position of test meal in six hours.

The filling defect is the most valuable as it is constant and is not affected by stomach peristalsis. The various characteristic undings are shown in

The various chara tensitic findings are shown illustrations accompanying the article

The diagnosis of gastric ulcer is similarly based on radiography and fluoroscopy. In the ase of chronic ulcer the following signs are basic: (1) per manent irregularities in control of stomath or cap (2) interruption of pensialise contractions: (3) in clsura and (4) locating pain directly over delect (fluoroscopic). Hollas L POTTER

Paimer C. L. The Significance of Certain Roent genographic Findings in the Gastro-intestinal Tract J in M 1: 001 403

Normally the stomach can change its position without the help of alteration in body posture. When this mobility of the stoma his lacking it is either due to restraining forces which prevent the movement or else to lack or power to mo e. The former is the most frequent cause for lack of change of position of the stomach.

Persist nt supraposed stomach is due to a re

traint and not to lack or power. This restraint is most frequently exercised by adherers the hield to help the form appending that transmant mental and results.

Mann F C. A Study of the Gastric Ulcers Following Removal of the Adrenals J E p M d = q t = m ≈ t

Mann noted at autopsy that animals dying after the removal of both a frenals showed a rute ulceration of the gastric mu osa in a large number of cases and he states that other investigators ha e noted similar results. As no lesion of the gastric mu osa was found at aut. psy in a series of more than roo practically normal animals, it seemed to the author that spontaneous ulcers were not common in these animals. He therefore ubjected large series of animals to administration of the results.

were studied. The lesions he found in the gastric mucosa after death from advenal insufficiency consisted of two main types, o e a wide-spread super ficial erosion the other a true punched-out ulcer formation. The gastric erosions practically always occurred in the fundic division and in most cases, the author states the pyloric mucosa appeared normal. The depend mucosa was usually congreated in the adrenalectomized animals, and in several instances there were definite ulcers. These duodenal ulcers occurred fust distal to the pyloric ring and appeared like cauterized areas about 1 s cm. in diameter They were deeper at the center than at the edges, penetrating to the muscularis mucosa at the center and they showed no evidence of hemorrhage.

To summarize briefly cute ulcers of the gastric mucosa are found in a large percentage of does and cats dying after drenalectomy These ulcers seem to develop during the moribund period. They are apparently peptic ulcers forming at the site of local hemorrhages in the eastric mucosa. They are tru acute ulcers, usually pen trating to the muscularis mucosa with a total loss of epithelium. They de velop in the beence of pancreatic secretion and bile However they appear to develop only in an cid medlum. GEORGE E. BEILEY

Friedenwald, J. The Modern Method of Treat ment of Discusses of the Stomach. There's Gen. 9 6 xl, 77

The treatment of diseases of the stomach was discussed with regard to the use of the stomachtube, with regard to the diet, to the use of medicinal gents, of mechanical supports, of mineral water

cures, and with regard to surgical measures. Freidenwald classified the indications for operation under three beads, as follows

Gastrostomy is indicated in Obstruction impermeable stricture of the cardiac orifice o of the esophagus. In benign obstruction of the pylorus pyl roplasty gastro-enterostomy or py lorectomy is indicated. I malignant disease pylorectomy is indicated for cure and gastroenterostomy for relief

a Gastric edeer The indications for operation are perforation, pyloric obstruction and ulcers resisting medical cures. The operations indicated are excision of the ulcer pylorectomy pyl roplasty or gastro-enterostomy

a Gastric carcinoma. An exploratory incision should be urged in all cases over 40 years of age with manifest symptoms of indigestion which are not relieved by few weeks of medical treatment and in which the diagnosis is still doubtful after a thorough examination. I W TURNER.

Case, J T Roentgen Studies After Gastric and Intestinal Operations. J im M Au lrv 638.

For several years Case has pursued the roent genologic study i patients after gastric a d in testinal operations. The results of this st dv are given under the headings (1) Acute small bowel obstruction, (s) gastro enterest my (t) appendec t my and (4) fleocolostomy

Experience has shown the value if roentgen examination in the diagnosis of post-operative acute small bowel obstruction with special reference t the decision as t the advisability if surrical interference. No barium or opaque meal is usually given, the observations being made by the gas

distention of the intestine

After sastro-enterostomy it has been believed that the rapid exit of food from the st mach was prevented by the formation of rythmically contracting constriction rings in the deodenum. The author has observed analogous action in a large number of cases in which the ordinary gastrojejunostomy had been performed viz sort of sphincter action established in the jejun mat a point varying from s to 6 ccm, below the gastroiciunal neni g

Case says that after gastro enterostomy there is st gnation of food in the jej um near the site of the gastro ent rostomy due t the inhibition f onward peristalt c act vities at this point.

The occurrence of occul stasis following anpendectomy is very common. Case believes that retention occurs t the sit of the st mp of the appendix, and that I has some relation to the invaginating suture by which the stump is usually burled.

Most of the cases examined all in fact except those cases in which a last ficial ileocolic valve had been formed ha e shown i compet ney of the ileocolic stoma permitting in enema to flow back into the small box I as will as etrogradely around th colon to th execum as far as the tump of the colon. In long operated cases especially there is very definit ileal at sis

From his studies Case states that in very considerabl percentage of cases i which the operation of ileosigmoidostomy is performed for the relief f intestinal stass, the end result i infinitely worse than if the patient had not been operated on at least as far as the stasis is con erned

H. LES E. Portna

Downes, W. A. Operative Treatment of Pyloric Obstruction in Infants; Review of Sixty-Six Cases. Surg G orOnier o o xrdl (

The author report 66 cases operated pon i five and one-half years. All presented the charcteristic symptoms. A tumor was palpated in every case before operation.

The theory best explaining the symptom-comple is that a true malf rmation is present at birth con sisting of a abnormal thickening of the circula muscle of the pylorus, and t this is added a ordematous condition some ten days, o late after birth. The cedema probably esults from th increased activity of the stomach necessary t force an increasing amount of food through the narrowed and elongated pyloric lum n

Gastro-enterostomy was performed upon 31 of the 66 cases the remaining 35 being operated on according to the Rammstedt method. Of the 31 cases in which gastro-enterostomy was done there were it deaths—a mortality of 5 per ent. Of the 50 discharged as cured. afterwards died of gastro-enteritis and 1 died of diphthera. The remaining 1 are well and have developed normally. Roentgen-ray examination shows the stomata working satisfactorily and little or no bismuth passing through the pylorius.

Not satisfied with the results from gu tro-enter ostoms it was decided to try the partial pyloroplasty of Rammstedt. Consequenthy this operation has been done in the last it cases. In this series there were 8 deaths a mortality of the cases discharged as cured has e died in e

cases discharged as cured ha e died in e lea ing the hospital the remaining c are well extending over a period from a few weeks to one and one half years. In no ase has there been a return of the symptoms

The cases operated on ac rding to the Rammstedt method vomited less and were easier to feed after

operation

The advantages of the partial pylor plasty over gastro-enterostomy are (1) time onsumed for operation the former requiring less than half the time necessary to perform the latter (the operation tequires much less surgical skill than gastro-intestinal tract is preserved. Roentgen ray aim nation one and one-half years after operation and autopay on one case dying three months after operation demonstrates the fact that the stoma h functionates normally and that the tumor entirely disappears after this procedure.

Jefferson G Ulcer of the Duodenopyloric Fornix.

As is well known, duodenal ul ers have a peculiar partiality for that part of the duodenum immediately adjoining the stomach and the probable role of the ga trie juice in the production of these ulcers is obvious. The pylorus when viewed from the duod enum appears as a knobbke pr jection formed by the massive muscular ring which constitutes the The furron which surrounds pylone sphineter this knob is termed the duoden pylon formix The depth of this sul us varies considerably being shallow in relaxed hypotoni stomachs and espehally well marked in fundenal ulter where gastric hypertonus is the rule. Uning to the absence of valvulæ connivent's in the uprapapillary duod enum the examination of the interior of this part is relatively easy and it is almost imposible to overlook an ulter unles it be ituated on the posterior wall and hidden by the projecting pyl rus

The auth r believes that the duodenopyloric lorinx is a frequent it of ucler and that ulcers u ually la sed as pyloric a term which uggests gastric rigin are reall duodenal. Chroni ul rif the stoma hr rely in 1 e th. pyl ri canal mest them being some datance ir in the pyl ru while duodenal uler become mor trequent as the pyl ru is approached. The result of uler in this location is the destruction of the unal land harkmaxing it very lufficult to tell the exact point of rigin 1 uch an uker. Cases are now on record in which the duckenal uler has been quite bealed

hile it invasion of the plrus has become magnant. The great difference in the frequents of arm ma foll sing duodenal and gastri ulir makes biferentiation extrem to important.

GATEN D

Brian R. C. Ulcer of the Jejunum 6

I'll er of the jejunum is apparently a mos r ce nh ion there being only four mass recorded in the literature with harove d rm and independent rate pre nu gastro-enterostom. The author case was that of amandy earst old with a last no titler ear duration or gasting pain which had been lugger used as offer of the duodenum. He was old eith taken with severe abdominal pain it liked by collapse it hours later operation was performed. The stomach was bound d with hard art pluguled to the left and firm. About in hes from the duodenouguand junture a round puin hed-out uller about the size of a cherry stone was it und. The patient dued the following morning.

Diagnosis of this condition apparently must be based upon deduction derived from observation, of jejunal ulcers forming after a previous gastro-enterostom. According to the more recent though the desired develop from autodigestion of the mucosa by an axid action which has been poorly modified by the alkaline products of the upper guit.

This has in a measure foon proboral I be the experimental work of Exalo Kathe Wallenstein and more recently by Cores of Ve. Vor. Wilke has done some interesting experimental work on dogs in which he performed gastro-enter stomme a limin, tering variou, amount of he frontier a distribution to the ground of the condition and with the table of the proposal of the condition also with the tate limits plastic at the gastro-intestinals elevostein has of Krompecher. In appropriate case, or from resection, or enterection, are apparently the operations of choice.

Dea er J B Acute Appendicitis \ I 1/ /

Appendictus is the most omm natical blan national minimum and the appendix constitutes the axenu by way of which index names commonly my does the upper at former. There are three peritorial february in relation to the appendix his hid wook the floorexial and the ubexect the ppendix being occasionally burned in no of the lat two thus explaining why the regain is believed to be been. The author has not refuded to find an appendix in the main base, he be operated upon

The appendix may be found below and t the outer side of the curcum, to the outer side of the cercum and colon, pointing upward and outward behind the crecum pointing upward to the inner aide of the cocum lying beneath or above the ter minal mesentery of the ileum and pointing down ward, occupying the false and even the true pelvis Thus the location of the point f tenderness and f referred pain must differ in particular cases, and syraptoms pointing to gall bladder duodenal, pyloric, pancreatic, or pelvic disease may arise.

The eti logical factors of importance re age previous attacks of appendicitis, catarrhal conditions of the gastro-intestinal canal, infectious diseases, especially influenza and digestive disturbances, the latter resulting in a great increase in the bacterial

flora of the intestine.

The perito rum defends itself by the functi n of exudation and absorption, the former enabling it to form adhesion of protective character and any treatment that breaks down these adhesions, such as purgation, defeats that protective function and may be harmful in the extreme

Appendicular becesses are met with in several situations () in fro t of below and to the outer side of the cream, the pus being confined by the crecum, small bowel, omentum, etc. (2) to th outer sid of the carcum and ascending colon or be hind the cocum in the layers of the mesocolon (a) in the pelvis (4) near the median line to the median side of the caccum (5) free in the abdominal cavity or existing in the shape of many pockets between the coils of i testines. In addition there are seen secondary abacesses, which occur close to the original abscess, reskiual abscesses occurring at the site of the primary bacess, and metastatic abscesses, which occur at any point distal to the site of the

original, r as a parotid abscess, pyclophiebitis, etc The clinical history is typical, a previously well individual being seized with acute and minal pain, first referred to the umbilical or epigastric region and accompanied by vomiting. The pain soon and accompanied by vomiting. The pain soon becomes localized to the right files fossa and muscular rigidity is noted. If this sequence is interrupted, the diagnosis of acute ppend citis may be doubted. Fever is always present. If the ppendix is in the pelvis the pain is likely to be left-sided. Suddenly subsiding pain followed by a chill points to gangrene, while exquisite tenderness denotes the presence of pus. The differentiation of importance lies between acute cholecystitis and

appendicitis.

The treatment is comprehended in the following points () examine the patient thoroughly and not through the clothes () give no aperient medicine
(3) /p to /n grain of morphine will not mask the symptoms and may be safely given when the pain is severe (4) the diagnosis having been made the proper measure is immediate operation. In the presence of peritonitis and in the absence of operation set the patient up in bed give nothing by mouth place an ice-bag over the tender rea, and institute enteroclyms. Operate in the cases of localized peritonitis where the lesion can be local ized and there is peristals in the surrounding region of the abdomen In diffused peritonitis defer operation until the pentonitis becomes a localized E. K. ARMSTROYO.

M yo, W J Radical Operation for Cancer of the Rectum and Rectosiamoid T Am Surg tes Washington of My

discusses () operability (s) operative The tilh mortality (3) operative duability (4) f netlon fol lowing operation, and (5) permanent cure, on the basis of a study of 753 cases of cancer of the rectum and rectosigmoid exami ed in the Mayo Clinic 803 and December 3 19 5 between January Of these, 43 were subjected to radical operation

Six hundred and nineteen cases gave an perability f 53 pe cent Rad cal operation was seldom refused because of the local extent of the disease. Had it been possible t know the extent of the discuse p eviously in some instances patients would not have been operated on, though many in a very ad anced stag were cured. Lymphatic in-volvement is usually lat and in no case was lymphatic extension alone the cause of inoperability Theoretically the abdominal cavity should be explored in every case because of the frequency of metastasis in the liver and perito cal cavity. In very bese patients the posterior kraske operation in one stage may be wise

In 43 radical oper til ns the operat re mortality was 15 per cent. D mor the last three years, in spit of the f ct that 7 8 pati to in each oo were operated on, the mort lity has been red ced to 125 per cent it has now been brought to about to ner cent. In cases in which the disease in the rectum was movable the mortality was oder 5 per cent \!! patients dying in the hospital a c classified as cases of operative mortality without regard to length of time that death occurred after operation. Necropsy was secured on 95 per cent of patients dying in the hospital The mortality in any given statistical roup is low with low operability high operability includes cases of advanced disease which greatly Increase the mortality Comparative statistical data of operative mortality means nothing unless the total number I patients examined whether operated on or ot, is taken into consideration,

The causes of operative mortality re (1) sepuls 39.8 per cent, usually due to solling of the operative field with the infected co tents of the involved bowel because the rectum had become fixed and the growth had penetrated its walls () nephritis, 3 per cent acute developing on chronic (3) metastatic tumors undiscovered on exploration, 1 5 per cent (had the true condition been known operation should have been performed) (4) death from hiemorrhage 6 t per cent, in no case immediate, but blood-loss led t exhaustion, sepsis, etc. No case of shock without hemorrhage. Secondary hemorrhages were not truly secondary but rather a continuation of badly controlled harmorrhages (5) death due to exhaustion etc. often some days or weeks aft r operation.

When aspetic healing took place patients were discharged from the hospital as early as sixteen days and returned to work in thirty days Infected wounds healed in from four to twelve weeks but the patients were not able to return to work for three or four months.

The best function followed the tube resection described by Balfour and the C. H. Maso method of direct end to-end union. The Wier invagination method gave excellent results when it could be used. In the Grip so operation although the entire sphinier was removed the functional results were as a rule excllent. In the majority fraves the radical operation necessitated a obstomy in the abdomen or a posterior anus mort or less un controllable. The Mixter midling colosiomy proved most antifactory.

As to permanent tures of the 430 pattent on whom a rescention was done 364 recovered from the operation. Eliminating those who were operated on less than three years ago 333 per cent have lived here years or more and 253 per cent have lived he years or more after the operation. These per call ages may be fairly in reused to 3 and 358 per cent respectively by subtracting from the mortality figures the normal death rates for cresponding ages for periods of three and five varsite 42 and 75 per cent.

LIVER, PANCREAS, AND SPLEEN

Collins, C. U: Indications for Cholecystectomy and Cholecystostomy Ill nos M J o 6 vi s o

Letters were sent to 14 patients who had recovered from choicy stosiomies asking if they
had had any trouble with the gall bladder or stom
ach since the operation. In all 102 replies were
received 74 said they had been perfectly well so
far as the gall bladder and stomach were concerned
15 complained of some pain in the gall bladder or
stomach or both while 14 complained of still
having severe pain at times in the region of the
gall bladder or stomach or both.

Conclusions are drawn from 196 cases

The presence or absence of stones in the gall bladder should not be considered in deciding to remove or leave a gall bladder. It is entirely a question of infection

z An infected gall bladder had better be re-

- moved if there are no contra indications.

 3. The location of a stone in the common duct may be a factor in the decision. If it has caused a recent attack of jaundice a possible pancreatitis should be considered and if present the gall bladder should be retained and drained at least temporarily.
- 4 An acutely inflamed gall bladder du to a rulent infection e aden ed by the clinical nymptoms had probably better be retained and drained

Icdico acta rual mortality investigation t blo

Ach legy testomy is safe tin they all the state of in helps testomy. A hole year they may be safely don after the source sympton has suball title in necessary.

Mapes, C. C. Uncertainties of Understanding Anent Cholelithiaal 1m / Sn e 6

The author reaches the following con lu-

t That there are many unlert i ties of und restanding an nit the et ology hist spathology symptom tology and treatment of choles that

2 Th t th hypothes that bat lal s vasion

represents the terminal rather than the primary f ctor in cholelithiasis has been clearly disproved.

3 That the medicinal treatment of cholelithiasis is defusion, there being no drug which internally administered will cause disintegration of definitely formed choleliths.

4 That the most f vorabl results may be expected to accrue from cholecystostomy cholelithot

omy and temporary drainage.

5 That cholecystectomy is illogical and unwar ranted except where the cholecyst is already damaged beyond hope of functional restoration or is involved in demonstrable malignancy C. G. Harro

Einborn M. Pancreatic Ston Colle (Zur Klinik der P. nkreauteinkollk) Berl. Hi Weksselr

0 6 Ш, о.

Pancreatic stones are rarely beeved in the human organism and their diagnosis during life is rarer still. Fit horn reports two cases which he has had under his observation.

Of the diagnostic signs the occurrence of coile IR, pain in the repigately region which is associated as in a translent prevarance of sugar in the urine is the most characteristic. This pain is periodically repeated and its sudden creation species of the passing off of the tone. The appearance of a st. e. in the freces consisting chiefly of calcium carbonat without cholesterin r bile pigment points to its pancreatic origin.

As a general rule the pancrentic function is not discount bed for a long time. Later there are dist beances which leasen the pancreatic activity. While the occasional appearance of sugar in the urine during an attack of colle is very important, it is not a time qual me in the diagnosis of pancreas stone.

If the ordinary methods of medical treatment fail and att class are frequently repeated and become more severe in horacter, operatory interference is indicated. The gall bladder and pancress should be carefully examined and if stone is present it should be removed. Frequently the palpation of small stones even in the exposed pancress is not possible. The gall-bladder should strays be drained because much drainage has a favorable effect upon an exist ing pancrestitis in the case of calcult.

Mayo, W J Th Spleen; Its Association with th Li er and Its R Intion to Certain Conditions

of the Blood J. Aw M. Ar. 9 6 levl. 7 6. The regularity with which splenke enlargements and other physical changes occur in association with diseases of the liver and of the blood has strongly impressed the author who, whenever possible during an absominal action cannines the spleen. The examination of this organ by external r can is often misleading and can never be relied on, although the \(\text{V-ray}\) offers some hope in the duagnosis of splenic posthology.

Investigation has shown that not only does the spleen extract bacteria and other toxic agents

from the blood but also merves the food value of broken down blood. Its by sending their remains to the liver f i ribs laboration. By whateve the function if the split is to the liver This close associate is will be by the splenic hypertrophy attends to liver the split is to the liver any liver cirrhosts in the B to the order any liver cirrhosts in the B to the order angular.

That the liver may ad quit ly find this function of conservation to his girth power of regeneration. In lithing the body this power is putially a hypertrephy

taking its place

Adami points out that in the leventh term that have escaped the leuroviers leventh giving rise to pigmented areas, and vaugh the theory that hacteria re of excellent parasition organisms, and that duestes the phode and the preventive serums to the cell of the body trestian upget it organisms and to so change the body per the they are no greateristic food.

Rosenow further demonstrates the select finity of bacteria and othe s bat ces for ertain tissues or organs. Is it not probable that the pilen has the power fittracting certain substances the blood as shown by splenic enlargement.

typhold malaria, etc.?

Moreover the spleen has no netraal secretion as removal does not deprive the body on import a constituent, nor is it u der complet nervous constituent, nor is it u der complet nervous constituent, nor is it u der complet nervous constituent house between the does, be ever contain m ch n n triatted muscle which is possibly responsibil for the deposit we hybring change in size.

As to the relation of the spleen t blood, normally in the focus, the pleen I ver d noid and lymphoid structures are blood-producing organs this power in the spleen at birth, diminishing to the

production of white cells.

In the various anamilia, the spheri acts as gravyard for the blood-rells, specially the red, in it through its own initiative but as though the copuscies were studited in some other place and destroyed in the sphere. Thus the enlarged spheris so often found in these conditions may be work of hypertrophy and it would appear that possibly this everes of spheric tissue or hyper-plenium, may cause an unnecessary destruction. It the red cells there bell groups extract the condition of spheric bell groups are the spherical properties of spheric ary anamilia in syphilis particularly of the liver by the removal of the charged splere.

In so-called primary tuberculosis of the spleen the removal of the organ has occasionally benefited a few. It is likely however that the disease is never primary in the spleen, and such diagnosis is rather the result of insufficient clinical study.

In the ansimla of chronic syphilis remarkable improvement followed the removal of the enlarged spleen. In chronic septic conditions with enlarged spleens removal does not bring satisfactory results as there is usually a very lowered resistance and a cardiorenal insufficiency to overcome In splenic enlargements associated with hepatic

disease it is often impossible to letermine whith r the process is primary in the spleen or liver. In Hanot's currhosis when diagnosed unloubted benefit follows removal of the spleen

In 4 cases the author has removed an enlarged spleen in onditions of portal currhous of the h

with much relief of the symptoms

It must always be borne in mind that the spleen is only one avenue of entrain e to the liver for nor sous agents but no matter in what manner hepatic disease occurs there is usually a concountant splenic enlargement.

The syndrome called splenic anamua the terminal stage of which is known as Banti a disease may be cured in many cases by removal of the spleen

Cases of stomach hemorrhage in which no other origin can be found should be carefully examined for evidence of splenic anemia as hemorrhage i one of the earliest symptoms in this condition.

In Gaucher's disease described by Brill al Mandelbaum it is the author's experience that splenectomy in the early stages is followed by a uncompanion of the splenest property stages and the splenest property stages are followed by a uncompanion of the specific splenest property stages are specifically s

In hemolytic jaundice which is of two types that of Minkowski and that of Hay m and Wildl splenectomy gives the most brilliant result

In pernicious anæmia remarkabl improvement follows removal of the spleen if I ne before the spinal cord changes occur

Preliminary to splenectomy and it is following it blood transfusion is necessary in the majority of cases. The donor's blood should always be tested with that of the recipient for agglutination and hemolysis. P M Carse.

Wahl, H R and Richardson, M L \ Study of the Liplu Content of a Case of Gaucher's Disease in an Infant 1 k I l M d = 0 6

The case on which this study is based was that of an infant eleven months of age with a chinal picture which in general, simulated Caucher's disease. The spleen liver and lymph nodes presented the usual changes but the unusual feature of the case was the almost complete substitution of the medulla of both suprareals by dusters of large pale valued that the latter were also present in Leyer's

pat hes in the intestines and in the thymus besides involving the adventura of some of the smaller viscel. The process was thus much more diffused that in any case hitherto described and also the first one described in an infant, when the condition may be more diffused than when it come in adults.

The author made an exhaustive study of the tissues of this case and an extensive review of the literature the t llowing onclusions being drawn

I In Cau her itsease the hir and the gleen show not only a mark din reuse in the lipin content tut also a seriou ult ration in vorral relations of the lipins to each other. The tixed fats are greatly redu. I while the lipoid uch a leithin and hilest roll ar greatly increased. In the ase tubed a leithin like body predominated but a holesterin compound may prese thin other cases.

2 In Caucher Issase lipord substances ac unulate in the firm of small droplets within the cytipla mofith tissue rells resulting in the formation and a cumulation of the littin tive large pale ell so hart it rite hit lorn ally of this dise see.

3 Can her a hastase is dutar disturbant of hipportain far in tabolism resulting in the a cumulation 1 hipportain far in tabolism resulting in the a timble large paid (if that are mostly tran.) rimed it indicate the large paid (if the large hipportain distribution of the large paid (if the large hipportain distribution) and the still tell of the liver. These cells have the physiology property of disposing of the fats and lipouds and comprise the and like I Statistical relappoints. It is thus a system disease. Fur involves the hematopoint organisonly secondardy in that they are very rich in the reti ulo-endothelial ells.
